STENOTAPE GELOSO

offers true "professional" dictating transcribing sound and efficiency

Doctor, Lawyer, Office Chief...here is the soundest practice you can establish to end paper-work problems. LISTEN: StenOtape gives you the greatest clarity of sound in the dictating field today. This 6½ lb. compact unit, with its extremely sensitive microphone records every word perfectly within a 30 foot radius. You can actually dictate comfortably from any point in the room. Seated and relaxed, you can tape interviews with a patient or client; and because of StenOtape's unique sound-fidelity, your secretary will hear and enjoy every word of your error-free dictation. Doctors and Dentists can play their post graduate educational tapes on StenOtape and enjoy superb playback quality. At the office, home or away, StenOtape records everything up to 2 hours on one tape...phone calls, conferences, dictation, *even music!* Hear the StenOtape difference now...it's an exceptional value!

only $179.95

FULL YEAR GUARANTEE Federal Tax Included

Check These Other Major StenOtape Features:

● Accurate word-counter. ● Built-in Speaker. ● 4" high, weighs only 6½ lbs. ● Travels in handsome attache case. ● Low-cost accessories available to cover every dictating-transcribing-recording situation. ● Precision designed by Geloso, Europe's largest integrated electronics manufacturer of communication equipment. ● Sales and Service Coast to Coast.

FREE! LIFETIME SUPPLY OF MAGNETIC TAPE MAIL THIS COUPON NOW!

AMERICAN GELOSO ELECTRONICS, INC.
251 Park Ave. So., Dept. 78, New York 10, N. Y

Gentlemen: Please rush, without obligation, illustrated booklet "The Facts About Dictating Machines." I understand that should I decide to purchase a StenOtape this coupon entitles me to a lifetime supply (6 rolls) of reusable Magnetic Tape worth $15.00.* **Offer expires July 31, 1960*

RETROLENTAL FIBROPLASIA AND OXYGEN THERAPY

The National Society for the Prevention of Blindness is receiving a number of inquiries regarding the relationship between oxygen therapy for premature infants and retrolental fibroplasia. Specifically, it is asked when the knowledge, that uncontrolled use of oxygen in the treatment of premature infants might result in retrolental fibroplasia, became generally available to the profession and hospitals.

Those who fail to follow recommendations established by competent authority for prescribing oxygen for premature infants subject their patients to the risk of blindness.

The entire medical profession and all hospital administrators have a duty to institute and persistently follow procedures in the administration of oxygen to premature infants that will prevent retrolental fibroplasia.

An annotated bibliography on the relationship of oxygen therapy to retrolental fibroplasia will be furnished on request. These references are set out in chronological order to show when it was that knowledge of the cause and prevention of RLF became available to the medical profession.

John W. Ferree, M.D.
National Society for Prevention of Blindness
New York, N. Y.
April 18, 1960

AN OPEN LETTER

Dear Dr. Carey:

Yesterday I listened to your vilification of the American Medical Association. Along with Senator Dirksen, I wondered how you ever got elected to your present position.

Let me call your attention to a few things you overlooked. Congress, regardless of the party in power, has never been able to get a compulsory health insurance bill out of committee for a floor vote *in either House.* Opposition within the Democratic Party has been strong, though you act as though only Republicans stood in the way of the program you espouse. *Senator Murray himself in 1945-46, when the Democrats were in power, did not report out his own bill from the Labor Committee.* This year in the Ways and Means Committee 7 Democrats voted against the Forand bill along with 10 Republicans.

The reason for opposition is clear. *The American people do not want State Medicine.* They have opposed the medical care systems of Russia and Great Britain. Intelligent people know that the nationalization of medicine would destroy the private practice of medicine.

You ask if the Social Security Act is socialistic. *It most assuredly is!* What else? The Forand bill is pure Socialism. If you weren't so ignorant you would know that the social security program in every country where it is in operation serves as the mechanism for Socialist control over the individual. Social Security is the foundation, the cornerstone, and the superstructure of the Welfare State. As Senator Dirksen said: *"You* like compulsion." Like the Senator, *I don't!*

Most of the old people about whom you claim to be so concerned wouldn't even be alive today if it weren't for the medical profession. Medical fees have risen along the present inflationary trend for which labor is so largely responsible. Hospital costs have gone up excessively because, in part at least, labor has put a higher price tag on all hospital non-medical services and on everything from bricks to steel and sheets to surgical instruments. Labor's demands have been excessive and selfish. You boost the cost of hospitalization and then yell about the results of your own handiwork.

Someone ought to *compel* you to apologize to the American Medical Association which is the professional organization to which most of the practicing physicians of the country belong. You are fully aware of the fact that the AMA has been meeting with citizen groups all over the United States in an effort to help solve the medical care problems of the aged. If organized labor were to give even a small fraction of the thought, time, money, and services that organized medicine has given to the aged of this country, there might be some hope of solving the complex problems involved. It would be an excellent idea if you were to shut up until you knew what you were talking about. Your colossal ignorance is matched only by your insolence.

Sincerely,
Marjorie Shearon
Editor, *Challenge to Socialism*

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

SCHOLARSHIPS FOR MEDICAL STUDENTS

The Montgomery County Medical Society, of Southeastern Pennsylvania, has launched a program of scholarships for medical students. This is hoped to be the beginning of a wide-spread attempt, by physicians, to reverse the rapid decline of both quality and quantity of applicants for medical schools.

Alarmed by well-documented reports from leaders of medical education, the Society did a committee study of

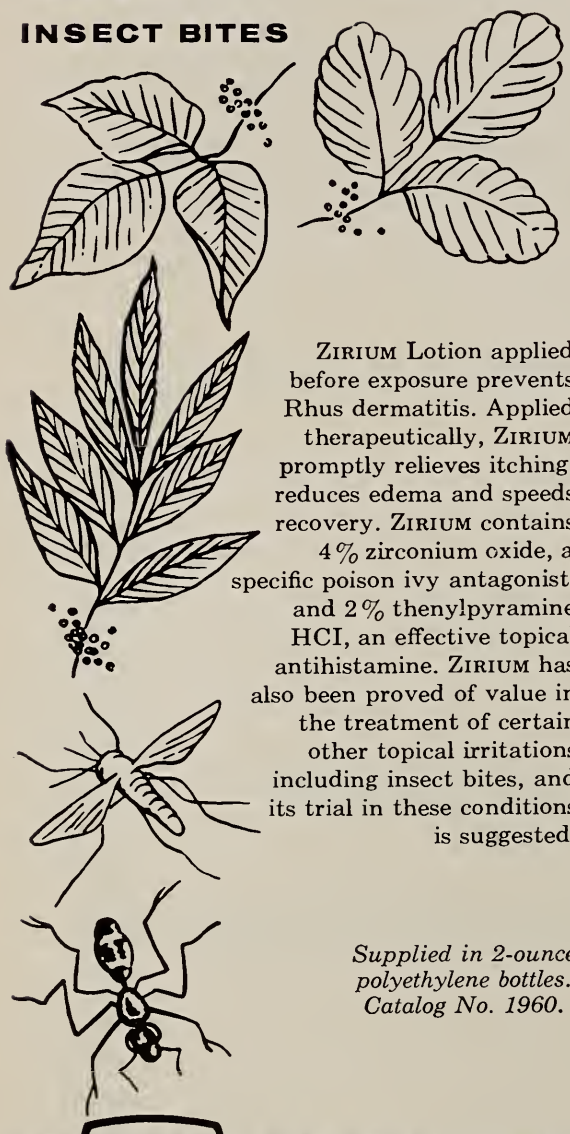
ZIRIUM



for relief of itching from

POISON OAK

POISON SUMAC

POISON IVY

INSECT BITES

ZIRIUM Lotion applied before exposure prevents Rhus dermatitis. Applied therapeutically, ZIRIUM promptly relieves itching, reduces edema and speeds recovery. ZIRIUM contains 4% zirconium oxide, a specific poison ivy antagonist, and 2% thenylpyramine HCl, an effective topical antihistamine. ZIRIUM has also been proved of value in the treatment of certain other topical irritations including insect bites, and its trial in these conditions is suggested.

Supplied in 2-ounce polyethylene bottles. Catalog No. 1960.

THE ULMER PHARMACAL COMPANY

MM-660b

(Continued from Page A-58)

the situation. It was found that the decline in medical school candidates had reached a serious level. Contrary to general belief, there are only 1.87 applicants for every seat in medical school freshman classes. The pleasant fiction that there are nine or ten applicants for each medical school opening has not been true for thirty years.

In addition the number of "A" students applying to medical schools has dropped off sharply. This trend is also shown in the recent rise in medical school flunk-outs. Academic casualties were 3.4 per cent in 1954-55, 5.6 per cent three years later.

The obvious conclusion, to the committee, was that medicine no longer is getting its share of first-class brains in its schools.

The causes of this problem were multiple. High cost of medical study, length of time needed for training, lack of scholarship funds, high marriage rate among college students, and intense competition from other professional fields.

Analysis of the temporary increase in applicants following World War II, confirmed the opinion that if money is available, the good college student is still interested in studying medicine.

BRUCE H. CARNEY, M.D.
Editor, *Bulletin of Montgomery County Medical Society*

MISREPRESENTATIONS

American Registry of Doctor's Nurse, 1366 National Press Bldg., Washington, D. C., has been charged by the Federal Trade Commission with misrepresenting that it is a non-profit organization, and with giving customers the means to misrepresent themselves as registered, graduate or licensed nurses.

Ralph Z. Bell, Robert L. S. and Evelyn W. Bickford, and Phillip Sellers, the concern's officials, also are cited in the FTC's complaint.

The respondents sell memberships in the organization, insurance policies, certificates, pins, emblems, and other insignia and indicia to persons employed in doctors' offices.

FEDERAL TRADE COMMISSION

ONE-HAND TALKING CHART

In January, 1943, I was stricken by coronary thrombosis followed by cerebral embolism, which resulted in right hemiplegia and complete aphasia. It was then, by using my left hand, that I devised twenty hand signs that became a universal one-hand manual language, well known as the "Hand Talking Chart" which has proven to be a practical clinical aid. With the chart, aphasia patients impart their basic needs and desires, thus dispelling their fears and helping them to a "come back."

During the last twelve years, the chart has been supplied without charge to physicians and nurses through the kind cooperation of medical editors, nationally and internationally.

In 1954, the "International Research Council" was chartered as a world-wide medical confraternity for the dissemination of knowledge concerning aphasia associated with hemiplegia. The aims of the Council include: (1) establishment of a clearing house on this specialized subject—library data, medical books, publications, and reprints of articles written by Council members; (2) the continuance of free distribution of the "Hand Talking Chart."*

*For a free copy of the chart write direct to Hamilton Cameron, M.D., 601 West 110th Street, Rm. 3-LL, New York 25.—Ed.

Sincerely,
HAMILTON CAMERON, M.D.

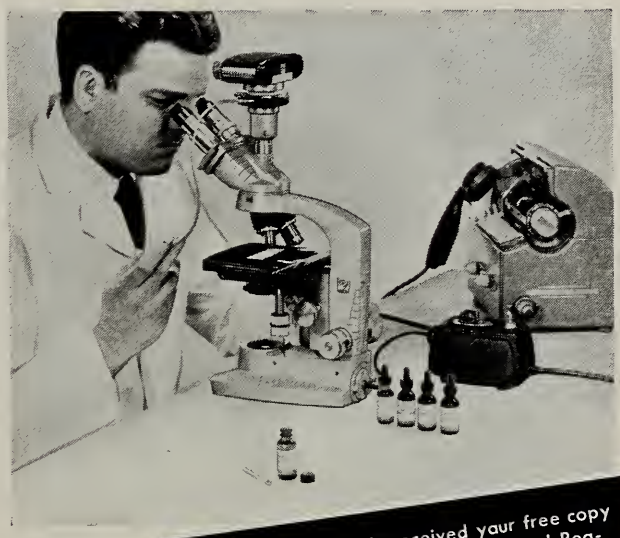
PUBLIC HEALTH SERVICE OFFERS NURSING RESEARCH GRANTS

The Public Health Service has announced four new grants totaling $137,616 for research in nursing. The new awards bring to seventy-seven the number of extramural projects which have been supported since the Nursing Research Grants program was established in 1955. The investment to improve patient care through research in nursing now exceeds $3,000,000.

The new awards are for studies in the areas of psychiatric nursing, public health nursing, behavioral science, and chronic illness.

More detailed information about the Research Grants program may be obtained from the Division of Nursing Resources, Public Health Service, Department of Health, Education and Welfare, Washington 25, D. C.



The death rate from TB is not dropping as fast as it was. Today, TB accounts for more deaths than all other infectious diseases combined.

LABORATORY REAGENTS and stains

New CATALOG
If you haven't already received your free copy of our new 64 page catalog of clinical Reagents and Stains, write for same today. It lists all of the more commonly used laboratory reagents and stains. You will find it very helpful.

ULMER REAGENTS AND STAINS HELP ACHIEVE ACCURACY

It is our objective to produce the finest reagents obtainable for clinical laboratory use. Their consistent accuracy saves hours of the technician's time.

Our scientific laboratory control is your assurance that Ulmer reagents are always fresh and meet the most exacting standards for each procedure. Every step of the manufacturing process is checked from the raw materials to the finished product. Moreover, our chemists are available to assist with any procedures with which you may be experiencing difficulties. Do not hesitate to call on them for assistance or advice.

For prompt and efficient service as well as guaranteed satisfaction, insist on Ulmer Reagents and order them direct from P & H.

The Physician's Diary

Dr. Richard C. Lillehei, University of Minnesota Medical School, has been named a Markle scholar in Medical Science by the John and Mary R. Markle Foundation of New York. The appointment includes a $30,000 grant to the medical school, which will use it to pay Lillehei supplemental support funds and to aid his research for the next five years.

* * *

The East Range Clinic at Eveleth has announced the appointment of **Dr. D. W. Davies** to the staff. Doctor Davies formerly practiced in Harvey, North Dakota.

* * *

Members of the Hennepin County Medical Society recently heard a panel discuss the relationship between emotions and heart disease. Participating were **Dr. Jesse Barron,** Minneapolis, Moderator; **Dr. Thomas W. Martingly,** President Eisenhower's medical consultant; **Dr. Ralph Rossen,** Director of the L. E. Phillips Psychobiological Research Foundation, Minneapolis; **Dr. Milton W. Anderson,** Mayo Clinic; and **Dr. Richard M. Steinhiber,** Mayo Clinic.

* * *

The new president of the Stearns-Benton Medical Society is **Dr. L. H. Wittrock** of Watkins.

* * *

Dr. T. M. Hanson, Albert Lea, has received word of his election to membership in the American Academy of Allergy. The American Academy of Allergy is an association of physicians interested in the care of patients with allergies, such as hay fever, asthma, some migraine headaches and some of the skin disorders.

* * *

Members of the hospital staff in Redwood Falls honored **Dr. W. A. Brand,** Redwood Falls, on his eighty-fourth birthday.

* * *

Dr. Robert J. Meyer, health officer for Golden Valley, announced that he is moving to Bethany, Oklahoma, where he will continue in medical practice. Doctor Meyer has been in Golden Valley since 1954. **Dr. Stanley Stone** and **Dr. Wallace Anderson** have taken over Doctor Meyer's practice.

* * *

The Karlstad Hospital staff will have an addition next fall, when **Dr. Duane Pansegrau,** formerly of Sioux City, Iowa, joins the group.

* * *

Doctors Lillian and Katherine Nye were awarded Honorary Life Memberships in the St. Paul YWCA at the annual meeting of that organization held April 25, at the YWCA Auditorium. The award was presented for extraordinary service and commitment. Dr. Katherine Nye has served as a member and examining physician since 1915 and Dr. Lillian Nye since 1921.

Dr. C. W. Mayo, Mayo Clinic, was the guest speaker at the annual meeting of the New Ulm Chamber of Commerce, May 2, in New Ulm.

* * *

The Virginia Municipal Hospital staff has elected **Dr. Hershel B. Cope** as Chairman of the Staff. Doctor Cope succeeds **Dr. L. K. McGill** as Chief of Staff. Other officers elected were **Dr. R. E. Payne,** East Range Clinic, Vice Chief of Staff; and **Dr. I. M. Prlina,** East Range Clinic, Secretary-Treasurer.

* * *

Dr. John C. Mickelson, urologist at the Mankato Clinic, was recently certified by the American Board of Urology. Doctor Mickelson is also a member of the American College of Surgeons.

* * *

Dr. Robert Cullen, who has practiced medicine in Wells for the past year and a half, has left on a speaking tour through southern and eastern states. Doctor Cullen was previously a missionary medical doctor in French Equatorial Africa.

* * *

Worthington physician, **Dr. R. W. Robinett,** has resigned his position on the Southwest Minnesota Mental Health Board, which administers the Tri-County Mental Health Center at Luverne. Doctor Robinett left early this month to assume duties with the University of Michigan Hospital at Ann Arbor.

* * *

The *Hibbing Daily Tribune* of April 22 featured an article by **Dr. Donald Nollet** regarding the fight against cancer. The article was in connection with the Cancer Control Month program for April.

* * *

Dr. George B. Eusterman received a high award, April 6, from the American College of Physicians in San Francisco. Doctor Eusterman was among five physicians to be made a Master of the College. He was selected by the Board of Regents of the College last November for the award for his "high accomplishments in internal medicine."

* * *

The medical staff of St. John's Hospital, St. Paul, held its annual spring formal dinner in the Town and Country Club, St. Paul. Co-chairmen were **Dr. Barnard Hall** and **Dr. Charles Beck.** Sponsors were **Dr. and Mrs. Gordon Strate and Dr. and Mrs. Donovan McCain.**

* * *

Dr. Robert B. Wilson, Mayo Clinic, was elected president of the American Society for the Study of Sterility at the 16th annual meeting of the group in Cincinnati, Ohio. The society was founded in 1944 to encourage study of the clinical aspects of infertility. Doctor Wilson will be installed as President at the 1961 meeting.

Dr. Paul G. Belau, Blue Earth, is one of eight physicians recently appointed to Fellowship at the Mayo Clinic in Rochester. His specialty will be diseases of the eye and eye surgery.

* * *

One of six American doctors who participated in the 27th Congress of Surgeons of the U.S.S.R. which was held May 23-28, in Moscow, Russia, was **Dr. Waltman Walters,** of the Mayo Clinic. Doctor Walters and his wife spent one month in Russia, touring cities and visiting hospitals, clinics, medical and surgical centers and research institutes. Previous to his visit to Russia, Doctor Walters attended the Pan-American Medical Association meeting in Mexico City, where he presented two papers.

* * *

Drs. Harry L. Berge, Edgar C. Burseth and **Willard F. Nordman,** Mora physicians, have announced that the Mora Clinic has moved to its new location on Park Street.

* * *

The Director of the Fort Snelling Veterans Administration Area Medical Office, **Dr. Oreon K. Timm,** has been appointed Deputy to the Assistant Medical Director for VA operations in Washington, D. C. Doctor Timm succeeds Dr. H. B. Cupp in the position.

* * *

Dr. Philip S. Hench, Mayo Clinic, was presented a new award by the American College of Physicians at its annual meeting in San Francisco. The award in the form of a medal, was presented to Doctor Hench for his discovery of the effectiveness of the steriod hormones in the treatment of inflammatory disorders.

* * *

An open house for **Dr. Fouad Sukkar,** Fulda, was held early in April to acquaint Fulda and area residents with Doctor Sukkar and the Clinic.

* * *

An estimated fifty doctors and their wives recently heard **Dr. John Grotting** speak on plastic surgery and **Dr. Joseph Cella** speak on problems of bleeding and hemorrhagic diseases. Doctors Grotting and Cella are from Grand Rapids. The event was the Spring Seminar of the Range Chapter of the American Academy of General Practice.

* * *

Dr. J. A. Cosgriff, Sr., Olivia, has announced the winners in the State Essay Contest sponsored by the American Physicians and Surgeons Association. Doctor Cosgriff also served as one of three judges for the state contest.

* * *

St. Paul physician, **Dr. A. E. Ritt** and his wife, visited the French Riviera, Paris, Italy, Switzerland and England this spring after attending a medical convention in Philadelphia.

* * *

Fort Lauderdale, Florida, was the scene of a Postgraduate Medical Refresher Course on "Mediclinics of Minnesota" which **Dr. Louis H. Wittrock,** Watkins, attended.

Here's the BIG news in professional liability insurance –

NO ADDITIONAL PREMIUM FOR PARTNERSHIP COVERAGE

and NO EXTRA PREMIUM FOR COVERAGE OF EMPLOYED PHYSICIANS OR TECHNICIANS

All other malpractice policies have an additional charge of 20 per cent or more of the individual rate to provide partnership coverage. Additional charges are also made in other policies by reason of the employment of other physicians, surgeons, x-ray or laboratory technicians. **Physicians & Surgeons Underwriters Corporation makes no additional charge for such coverage.** "Physicians & Surgeons" is administered by a medical Board of Directors. It is the FIRST COMPANY in Minnesota to offer this partnership and group practice feature, plus a rock bottom basic premium structure and a new broad comprehensive policy.

There are many other features in the Physicians & Surgeons policy that are built in for the protection of the doctor. Write or call today for complete details on this all-risk comprehensive policy.

Dr. J. V. Ross, Jr., Rochester, has been appointed to the position of staff assistant at the Mayo Clinic. Doctor Ross is specializing in Internal Medicine.

* * *

Dr. Leo J. Kanner, University of Minnesota visiting professor of child psychiatry, has been named recipient of the first annual award of the National Organization for Mentally Ill Children, Inc., according to Robert P. Marcus, organization president. The award, given for "significant contributions to understanding of childhood mental illness," was presented to Doctor Kanner at a dinner in his honor May 17, in New York City's Hotel Plaza.

* * *

Dr. Hugh R. Butt, head of a section of medicine in the Mayo Clinic, Rochester, and Professor of Medicine in the Mayo Foundation, Graduate School, University of Minnesota, was installed as president of the American Gastroenterological Association at the sixty-first annual meeting of that organization in New Orleans, Louisiana. Doctor Butt was elected to the presidency at the 1959 meeting of the Association in Atlantic City, New Jersey.

* * *

Dr. J. Arnold Bolz, Grand Rapids, has recently completed a book on a partial history of Minnesota's canoe country. His book, "Portage into the Past" will be published by the University Press this fall.

* * *

St. Paul physician, **Dr. Gordon R. Kamman**, addressed a meeting of the American Board of Legal Medicine at Cleveland, Ohio, April 1. Doctor Kamman's topic was "Sex Psychopath Laws and Related Subjects."

* * *

The East Range Clinics, Virginia, announce that **Dr. I. M. Prlina** has been certified by the American Board of Urology following a trip to Chicago for completion of Part II of the American Board examination.

* * *

Dr. George D. Molnar, Mayo Clinic, was guest speaker at a meeting of the Rochester Dietetic Association at St. Mary's Hospital in Rochester. Doctor Molnar spoke on recent studies on the management of diabetes mellitus.

* * *

The *Rochester Post-Bulletin* recently printed an article by the Mayo Clinic reporting registration figures. The report stated that total registration at the Mayo Clinic as of April 2, 1960, was down 772 from a year ago. However, administration sees no reason why registration figures may not improve in the coming months.

* * *

Dr. A. C. Forsland, Virginia, has moved into new offices located on 9th Street North in Virginia in the Northgate Plaza. Doctor Forsland held an open house in April for residents of that area to see the new offices.

* * *

President of the Minnesota Medical Foundation, **Dr. Herman E. Drill**, Hopkins, has announced that the Foundation has begun accepting applications for its 1960 scholarship program. Awards of $500 each are

made annually to medical students on the basis of scholastic performance and financial need. The awards are financed by private contributions of individuals, businesses and organizations and are administered through the Foundation.

* * *

The *Wabasso Standard* carried a feature article on April 14, 1960, concerning Wabasso's physician, **Dr. William Alcorn.**

* * *

Dr. Frank Kiesler, Minneapolis, has been named psychiatrist and program director of the Tri-County Mental Health Center at Grand Rapids. Doctor Kiesler will start his duties in early July.

* * *

The Hennepin County Multiple Sclerosis Chapter has named **Dr. Maynard Cohen** as chairman of the Medical Advisory Committee. Doctor Cohen is a University of Minnesota Hospital Research Neurologist.

* * *

Reelection of officers of the Northern Association for Medical Education has been announced. Reelected officers are **Dr. Davitt Felder,** President; **Dr. Edward Burch,** Vice President; **Dr. Ian A. Brown,** Secretary, and **Dr. Ben Sommers,** Treasurer. John W. Hedback, new Executive Director of N.A.M.E., was introduced to the Board at the meeting. Members of the Board are the elected officers and **Drs. Robert W. Holmen, Jane E. Hodgson, Albert E. Ritt, Charles C. Cooper, Milton Hurwitz, Gilbert P. Wenzel, Wallace P. Ritchie, John B. Coleman and Delmar R. Gillespie.**

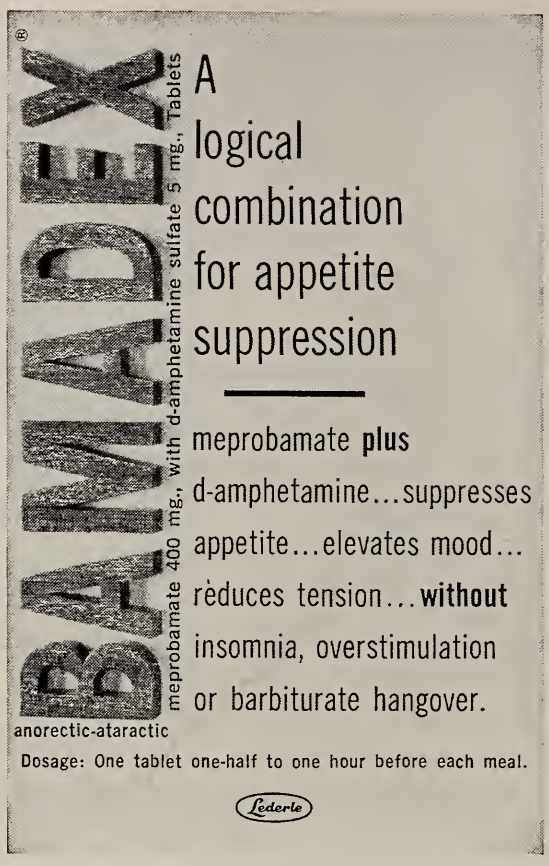
St. Paul surgeon, **Dr. Robert Flom,** recently conducted a "Demonstration of Cardiac Arrests" at a seminar for post-graduate students of the Southwestern Minnesota Academy of General Practice. **Dr. E. A. Kilbride,** Worthington, President and **Dr. D. E. Nealy,** Adrian, Secretary, were in charge of arrangements for the seminar.

* * *

Dr. and Mrs. J. C. Cain, Rochester, have just returned from Europe where Doctor Cain presented a paper at the Sixth Congress of The European and Mediterranean Societies of Gastroenterology in Leiden, The Netherlands. The Cains also visited Belgium, France, Germany, Spain, England and Switzerland.

* * *

The Fridley, Minnesota, Council has announced that **Dr. Earl W. Eli,** Minneapolis, has resigned as Fridley Public Health Officer. Doctor Eli stated his resignation was due to the press of business.



* * *

The section of neurologic surgery of the Mayo Clinic and the Mayo Association have announced the establishment of the Craig Memorial Neurosurgical Travel Award in honor of the former chief of the section, the late **Dr. Winchell McK. Craig.**

* * *

Forest Lake physicians, **Drs. G. T. Midboe** and **J. L. Purdie,** have moved into the new Doctors Clinic. The new building is located at 121 S. E. 11th Avenue, opposite the new hospital site.

Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

COLD INJURY, GROUND TYPE. By Tom F. Whayne, MC, USA (Ret.) and Michael E. Debakey, M.W. (U. S. Army. Surgeon General's Office. The Medical Department of the U. S. Army in World War II. Part 4) 570 pages. Illus. Washington, D. C.: Government Printing Office, 1958. Price, $6.25.

This volume is a remarkably frank discussion of the problem of trench foot, frostbite, chilblains and shelter leg as experienced in World War II. Historical data concerning cold injury is extensive and begins with Larrey's observations in the Napoleonic Wars. The errors of command in not training the combat soldier to care for his feet and in not providing the proper protective equipment are frankly pointed out. This discussion of the care and treatment of cold injury is excellent but most important is the great emphasis placed on the fact that the only treatment of worth is proper prophylaxis. It is hoped that this volume will serve as a useful guide for persons who may be subjected to conditions similar to those found in battle in cold climates. Physicians who deal with vascular disease problems will find this volume of great value. F.M.O.

MINNESOTA BLUE SHIELD

A Philosophy of Service

The Minnesota Legislative Act providing for the establishment of Blue Shield in this State declared: "It is the purpose and intent of this act... to make possible a wider and more timely availability of medical care, thereby advancing the public health and the science and art of medicine in this State." The philosophy of service expressed in these words continues to guide Minnesota Blue Shield today.

Fibrous Tumors of the Soft Tissues

ARTHUR PURDY STOUT, M.D.
New York, New York

From the Laboratory of Surgical Pathology, Columbia University, New York, New York.

Read at the Sectional Meeting, American College of Surgeons, Minneapolis, Minnesota, April 13, 1960.

ONE MIGHT suppose that tumors composed of fibrous tissue should be easy to recognize, should be easily divisible into benign and malignant, and their behavior easy to predict and to deal with. Actually, they are not so easy to identify and are a frequent source of error and confusion. One important reason for this confusion stems from the fact that it is common to suppose that a fibroblast is a simple cell that makes connective tissue fibers and is derived from a pre-existing fixed connective tissue called a fibrocyte. This is not necessarily the case, for there are a number of different cell types that are facultative fibroblasts. For example, it has been proved that Schwann cells, reticulum cells, histiocytes and mesothelial cells are all capable of acting as fibroblasts by producing reticulin and collagen and temporarily abandoning their proper functions.[3,9] A variety of other cells in tumors such as lipoblasts, rhabdomyoblasts and synovioblasts, by exercising their ability to function as fibroblasts, can produce tumors that may easily be mistaken for fibrosarcomas.[9] This might not be serious were it not for the fact that the malignant tumors formed by these facultative fibroblasts actually do not behave biologically like fibrosarcomas but like malignant mesotheliomas, rhabdomyosarcomas, liposarcomas et cetera, depending upon the variety of cell masquerading as a fibroblast. Each one of these malignant tumors has its own peculiarities of behavior and may be quite different one from the

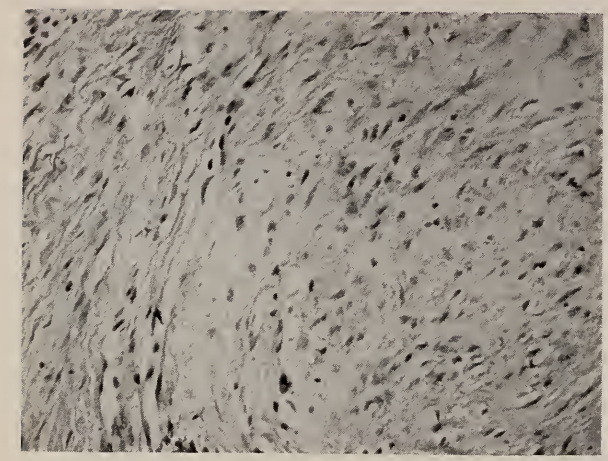

Fig. 1. Fibromatosis of the popliteal space in a child. X200.

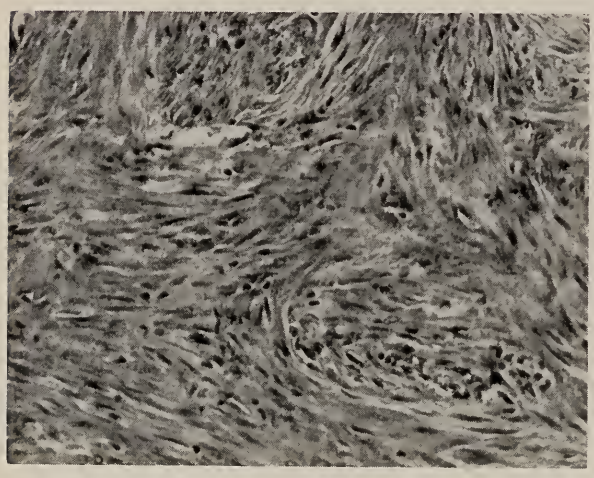

Fig. 2. Fibromatosis or differentiated fibrosarcoma of the arm in a child. A recurrence was excised after four months. Well fifty-three months later. X200.

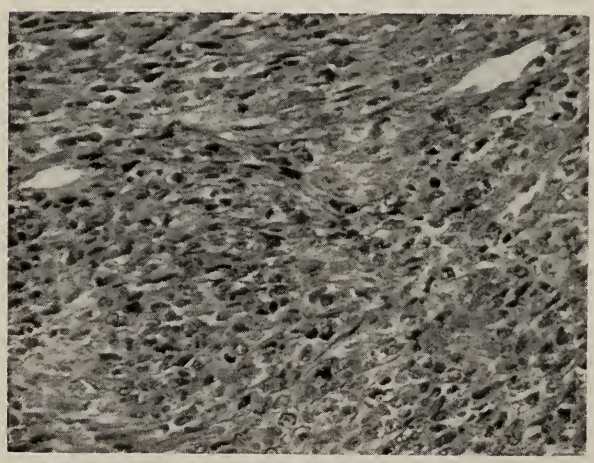

Fig. 3. Malignant fibrosarcoma in trapezius muscle of 14-months old child. Recurred and metastasized to lungs. X200.

other and from the true fibrosarcoma derived from honest fibroblasts. This phase of the problem is further complicated by the fact that sometimes cells of mesenchymal derivation seem to be unable to control their atavistic tendency so that they may form a single tumor composed of several different kinds of tumor types. There are both benign and malignant mixed mesenchymal tumor types that are called mesenchymomas and are most confusing to one not familiar with these potentialities.[9]

Another potent source of error and confusion derives from the fact that the term fibrosarcoma is often applied indiscriminately to both benign and malignant tumors. In a large majority of cases, the fibrosarcoma does not metastasize and is only worthy of the name because it is apt to infiltrate insidiously and therefore often recurs following incomplete removal. If this persisting infiltrative growth happens to occur in a part of the body where there are structures which cannot be sacrificed with impunity, the result may be loss of an extremity or even life itself; but this is not really an evidence of malignancy, but rather neglect on the part of the patient, or inadequate treatment on the part of the surgeon, or both. In 1948, when I published a paper dealing with fibrosarcomas,[8] I thought the term fibrosarcoma ought to be retained for these non-metastasizing tumors because our recurrence rate at that time was 63 per cent. But later I became convinced that one should attempt to apply the term of fibrosarcoma solely to the truly malignant tumors that commonly are capable of metastases. At the present time, therefore, most often I use the term fibromatosis[10] instead of fibrosarcoma for such lesions as dermatofibrosarcoma and others like it in the skin and elsewhere. This eliminates the term fibrosarcoma for many benign tumors. However, there are some tumors that are so cellular that one hesitates to exonerate them entirely. These are well differentiated, even though very cellular, in that they form many connective tissue fibers. For these I still use the term fibrosarcoma but qualify it by the descriptive word "differentiated" and explain that while it is remotely possible such a tumor might metastasize one need not greatly fear it. This leaves the term undifferentiated fibrosarcoma for the truly malignant fibrous neoplasms that often metastasize.

But not all sources of diagnostic confusion have been covered. The single or multinodular tumor that develops in the corium and often involves the subcutaneous tissues as well is not always a simple

fibrous growth. Sometimes it has a considerable vascular element and has phagocytic histiocytes intermingled. For such tumors, Gross and Wolbach[4] suggested the name sclerosing hemangioma disregarding the histiocytes as incidental. Others have felt that the histiocytes should not be regarded as incidental and use the term fibrous xanthoma for such tumors.[9] The issue has been further confused when it has also been suggested that some of these tumors are neurofibromas.[1] Clinically, such growths may be indistinguishable from the so-called dermatofibrosarcoma protuberans which in my opinion is a fibromatosis, or from the rare sweat gland carcinoma. But it is of some importance to make an exact histological interpretation for both the sweat gland carcinoma and the fibrous xanthoma very occasionally will metastasize while the dermatofibrosarcoma (that is, fibromatosis) scarcely ever does.

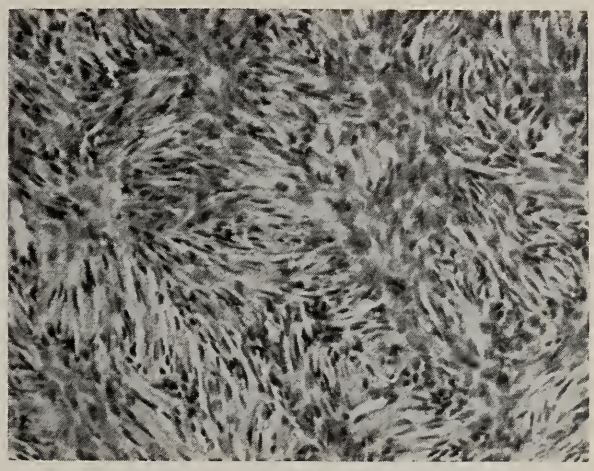

Fig. 4. Fibrous xanthoma of chest wall. The peculiar spiral nebular pattern is characteristic. Sometimes called dermatofibrosarcoma protuberans. X200.

In recent years, another fibrous growth has been recognized which, due to misinterpretation, has led a great many pathologists into the error of calling a benign lesion malignant, resulting in unnecessary operations. This is the so-called pseudosarcomatous fasciitis.[2,5,7] This fascinating lesion, first accurately described by Konwaler, Keasbey and Kaplan[5] in 1955, appears to be a relatively recent development, for I have been unable to find such cases in our files prior to 1948; yet at the end of 1959, we have records of seventy-seven cases, thirty of which came to us in 1959. The information concerning these patients is shown in Tables I to IV. Briefly, the lesion appears suddenly, and usually unheralded, as a rapidly growing subcutaneous lump that may be painful or tender. Probably because of the sudden appearance and rapid growth, the patient seeks early relief and the surgeon removes it. Then the trouble begins, for often an unwary pathologist calls it a malignant tumor. I can easily understand this, for I did the same thing before I learned to recognize the lesion. The growths, which seldom reach a large size, are generally adherent to the deep fascia and are composed of a peculiar mixture of fibroblastic tissue with areas of capillary proliferation, sometimes fat necrosis and a very variable number of inflammatory cells. Actually, the lesion appears to be some kind of a granuloma with a bizarre cellular proliferation that has variously been called fibrosarcoma, liposarcoma, Kaposi's sarcoma, cystosarcoma phyllodes and sarcoma of undetermined type. Fortunately these diagnoses have not led to any amputations as far

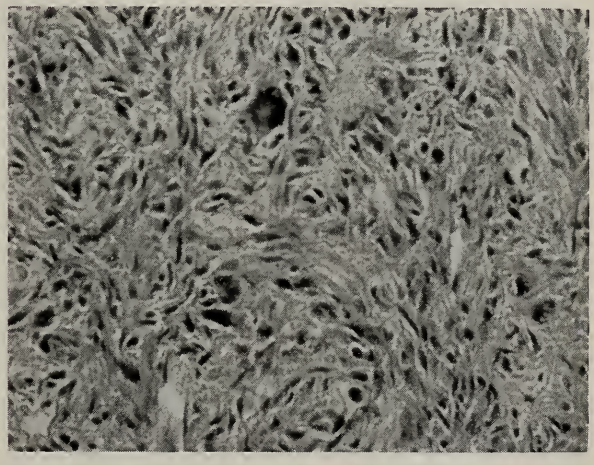

Fig. 5. Fibrous part of a liposarcoma. The pyknotic giant cells betray the nature of the growth. X200.

Fig. 6. Pseudosarcomatous fasciitis. This benign granulomatous lesion was called erroneously a synovial sarcoma. X200.

as I am aware, but there have been a number of unnecessary reexcisions of the wound. I know of no case that has metastasized, and of only five that have had recurrences.

which are not hard to identify if one is familiar with them.[9] These features are now reasonably well known to pathologists, and they are much more careful of their diagnoses than was formerly the case. When one disentangles the pure fibrous growths from all the others, some very interesting features come to light, as indicated in Table V. This deals only with pure fibrous growths of mesenchymal tissues in children. I have chosen to use children because I am studying their tumors extensively at the present time and can give the information more easily. In general, I have found that the proportion of most of these mesenchymal tumors in children compared with adults with a

few notable exceptions is in the ratio of 1 to 7. With the exception of the fibromatoses,[10] no special efforts have been made to obtain follow-ups, and the reports of metastases concern only those cases in which the knowledge of metastases has come to me. Nevertheless, I believe it furnishes evidence

TABLE V.
FIBROUS TUMORS IN CHILDREN

	Number	Known Metastases

Fibromatosis	172	1
Pseudosarcomatous fasciitis	11	0
Differentiated fibrosarcoma	27	0
Undifferentiated fibrosarcoma	11	2
Total	246	3

that the only really reliable malignant tumors are the undifferentiated fibrosarcomas.

One other piece of information contained in this table is of significance and must be kept in mind. It will be noticed that one of the 172 cases of fibromatosis metastasized. This is the case of a young child reported by Prior and Sisson[6] with a most innocuous appearing fibromatosis in a finger. Nine years after the removal of the fibromatosis, similar lesions appeared in both lungs, and the child died. While it is conceivable that the lung lesions represented new fibromatoses, the probability is great that they were metastases. This emphasizes the fact that exceptionally a histologic-

ally benign growth may be biologically malignant. It must be of very rare occurrence, but the possibility must be accepted as an unpleasant fact.

Summary

It can be appreciated from the foregoing that the problem of the behavior of pure fibrous growths both in adults and in children has been a difficult one to evaluate for the various reasons suggested. One source of error has been the failure to take into account the ability of an array of different cell types to act as facultative fibroblasts, resulting in other tumor types having been falsely called fibrosarcomas. Since many of these other types are truly malignant metastasizing tumors, this has suggested that any tumor called a fibrosarcoma is *ipso facto* a neoplasm that will frequently metastasize. Actually, the large majority of tumors called fibromatoses or fibrosarcomas is highly differentiated and in spite of cellularity, scarcely ever metastasize. Only a relatively small group characterized by dysplasia and marked mitotic activity is truly malignant and capable of metastasizing. Such tumors are almost always found deeply situated in the subcutaneous tissues or deeper. In addition to mistakenly calling other types of malignant sarcomas by the name of fibrosarcoma, the mistake is also made of calling other varieties of benign lesions by the term fibrosarcoma, such as fibrous xanthoma and pseudosarcomatous fasciitis.

It is wrong to suppose, however, that because a fibrous growth is classified with the benign tumors it is harmless, for almost all varieties are capable of insidious persistent infiltrative growth so that their palpable confines never correspond with their actual extent. This frequently leads to incomplete excision and recurrence. In some parts of the body, and particularly in children, this has led to loss of digits, extremities and even life.

Since these growths must be treated by surgery because they are radioresistant, the surgeon is faced with a difficult problem: not only may he be in clinical doubt concerning a neoplasm, but even the pathologist may be deceived by the histological appearance of the growth. The following observations based upon long experience with soft tissue tumors may be of aid in helping the surgeon plan his therapy. These apply not only to fibroblastic tumors but to a majority of soft tissue growths beneath the epidermis. Almost without exception, these tumors are not encapsulated and grow by insidious infiltration beyond their palpable limits. This means that unless some apparently uninvolved tissue surrounding the tumor is removed with it, local recurrence will often take place. If one of these tumors metastasizes, it is almost invariably through the blood stream and very seldom through the lymphatics. Therefore the successful removal of all the local lesion will almost always effect a cure if done before metastasis has occurred. In an extremity, wide local excision is just as effective as amputation if it can remove a zone of uninvolved tissue on all sides. The secondary removal of tissue, because the operator finds he has cut through tumor tissue at operation, never has the same chance of cure as an excision that primarily never enters the tumor field, for the knife and other instruments can implant tumor cells anywhere in a wound just as they can carry bacteria. Any part of the wound, including opened tissue spaces, may receive the viable implants, and recurrence may ensue. If a tumor is very large, the writer believes it is wise to take a careful biopsy before undertaking treatment, for this may influence the type of treatment to be undertaken. For small growths, the excision biopsy, observing the proper precautions, is probably best.

Evaluation of a Nasal Decongestor in Pollinosis

CLARENCE SIEGEL, M.D.
Saint Paul, Minnesota

Dr. Siegel is in charge of Adult Allergy Clinic, Wilder Dispensary, Miller Hospital, Saint Paul, Minnesota.

IN FEW fields of medicine can the physician obtain such prompt patient satisfaction as in the treatment of pollinosis. This is especially true with one of the newer formulations available in a timed-release tablet containing a sympathomimetic of unusual duration of action, phenylpropanolamine hydrochloride,[1] plus two antihistamines, pheniramine maleate and pyrilamine maleate.*

The management of the allergic state involves providing control by avoidance of the offending allergen, specific desensitization therapy, and prompt alleviation of allergic symptoms. Sheldon comments on this point in an excellent review:[2] ". . . the problems facing every clinician when he first meets a patient with an allergic disease are that of immediate control of the patient's symptoms and a studied approach to prevent further attacks."

In addition to the desirability of correcting the basic cause of the allergy, it is important that the patient receive early relief of symptoms. This is imperative not only for the sake of patient satisfaction, but also to circumvent the appearance of dangerous sequelae to the allergic state. Allergic rhinitis, left unattended, may lead to development of asthma, nasal polyposis, recurrent frontal headaches, unrelieved tonsillitis, adenoiditis, and deafness.

Feinberg has reported that 30 to 40 per cent of patients with hay fever in the Mid-Western States will ultimately develop asthma.[3] Nasal blocking forces the patient to mouth breathing and exposes the bronchi to increased irritation by pollen. Also, the constant insult of offending allergens on the contact zones of the nasal mucous membrane gives rise to vasodilation and development of nasal polyps which may result in almost complete nasal obstruction and impaired sinus drainage.[4] Eighty-six per cent of recurrent frontal headaches are due to allergic conditions involving the nasal cavity.[5] These headaches may be prevented by proper diagnosis and treatment.

Early recognition and treatment of allergy in children may save some patients from unnecessary laryngological surgery.[6] Unsatisfactory results following tonsillectomies and adenoidectomies, which according to Kaiser and cited by Thomas, occur in some 50 per cent of operated patients, are largely due to allergic involvement.[6,7] Blank reports that a "common cause of deafness in children is thought to be due to serous otitis media which is now recognized as an allergic entity."[8]

This study was generated with the objective of affording *increased relief* to patients suffering from allergic disorders. In so doing, it was expected that greater patient satisfaction would result and that the appearance of dangerous and distressing sequelae could be circumvented or reduced in frequency.

Method of Study

One hundred and twenty-eight patients were studied in private practice during the late summer and early fall of 1958 to determine:

1. The incidence of upper respiratory allergy as measured by number of patient visits in relation to daily pollen count.

2. The degree of symptomatic relief afforded by a new decongestant-antihistamines formulation as compared to previous single anthistamine therapy.

3. The more satisfactory control of symptoms and reactions during desensitization.

Dosage

Wishing to use the minimum amount of drug consistent with good results, all but five patients

*Triaminic®. Each tablet contains Phenylpropanolamine hydrochloride, 50 mg.; Pheniramine maleate, 25 mg.; Pyrilamine maleate, 25 mg.; in a timed-release tablet. Supplied by the Smith-Dorsey Division of the Wander Company, Lincoln, Nebraska.

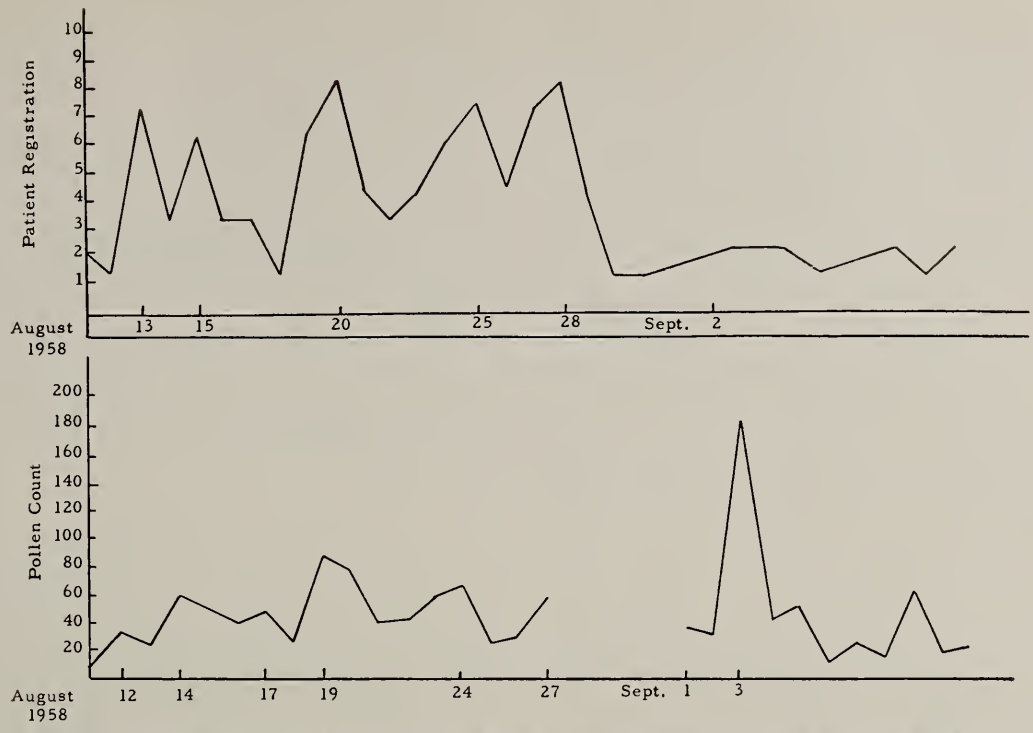

Fig. 1. Comparison of pollen count to patient visits for allergic rhinitis symptoms (showing possible relationship between increased pollen count and increased incidence of patient visits).

were started on one tablet b.i.d. The symptoms of the remaining five patients were so intense, it was felt advisable to place them on t.i.d. dosage to afford every opportunity for relief. Subsequent to initiation of therapy, of the 123 patients on b.i.d. dosage, four patients were placed on one tablet three times a day because of unsatisfactory response at the lower dosage level. Simplification of dosage was facilitated because this medication is available in a timed-release tablet affording six to eight hours of action.

TABLE I. DEGREE OF SYMPTOMATIC RELIEF OBTAINED WITH SINGLE ANTIHISTAMINE COMPARED WITH NASAL DECONGESTANT PLUS TWO ANTIHISTAMINES

Response	Previous Therapy (Single Antihistamine)		Present Therapy (Nasal Decongestant Plus Two Antihistamines)	
	Number of Patients	Per Cent of Total	Number of Patients	Per Cent of Total
Good	9	11.2	122	95.3
Fair	64	81.0	2	1.6
Poor	3	3.9	3	2.3
No change	3	3.9	1	0.8
Total	79	100.0	128	100.0

Results

Patient visits directly coincided with increased pollen counts. With the exception of the peak pollen count during the first week in September, the majority of patients requested treatment the same day or approximately twenty-four hours following days of high pollen counts (Fig. 1). It may be explained that the peak count on September 3, 1958, was not followed by a heavy patient load for the simple reason that most of the patients in this practice were under treatment prior to that time.

Of the 128 patients studied, single antihistamine therapy had been employed in seventy-nine during the previous allergy season (1957) with less than satisfactory results. It is readily apparent from Table I that the addition of an effective nasal decongestor and a second antihistamine contributed materially to patient comfort and protection from subsequent unpleasant allergic episodes.

The criteria used in judging degree of response are based on personal observation and patient appraisal. A "Good" response is necessarily a decided diminution of rhinorrhea, nasal obstruction, sneezing, lacrimation, and itching of the eyes and throat. Those patients who received some benefit, but lacking in degree and duration of relief, were classified as receiving "Fair" response. The "Poor" response group demonstrated little change in symptoms.

The symptoms of patients receiving concurrent desensitization were adequately controlled with the

decongestant-antihistaminic formula until such time that the patient could be maintained relatively free of symptoms without medication. This procedure has been found important because many patients seek desensitization therapy only when the

TABLE II. DEGREE OF SYMPTOMATIC RELIEF OBTAINED WITH TEST MEDICATION CONCURRENT TO DESENSITIZATION

Response	Number of Patients
Good	51

Poor	0
No indication	1
Total	52

pollen season is well advanced. In addition to specific desensitization, the allergic patient is deserving of the symptomatic relief afforded by this formula. The degree of relief obtained with the test medication concurrent to desensitization is well-illustrated in Table II.

Side Effects

An added advantage to this formula lies in the relative absence of side effects (Table III). This virtus is due to the pharmacologic balance between the soporific effect often induced by antihistamines

TABLE III. SIDE REACTIONS WITH TEST MEDICATION

Degree of Reaction	Number of Patients	Per Cent
No reaction	90	70.3
Minimal	35	27.4
Moderate	3	2.3
Total	128	100.0

and the slight CNS stimulation of the phenylpropanolamine HCl. Multiple histamine antagonists often reduce side effects without sacrificing therapeutic effectiveness.[9-12] This feature was valuable in this group of patients for most of them continued their employment or household duties without interruption throughout the allergy season.

Discussion

Highly satisfactory results were obtained with the oral decongestant at low dosage due to its timed-release feature. Experience has shown that continuous dosage throughout the day tends to call the patient's attention to his condition and during the night interrupts his sleep. The value of long-acting medication in the treatment of the allergic state has had previous documentation in the literature.[13]

It has been found that the oral administration of the sympathomimetic amine, phenylpropanolamine HCl, and the two antihistamines, pheniramine maleate and pyrilamine maleate, provides marked relief of nasal obstruction, rhinorrhea, lacrimation, itching of the eyes and throat. The degree of relief would seem to forestall the development of the dangerous and distressing consequences of the untreated allergic state. Greater relief was afforded the patient without congestive rebound.

Summary

A series of 128 patients, of which seventy had received only fair (or poorer) response to a previously administered single antihistamine, has been reported. Ninety-five per cent received good results on a product containing a nasal decongestant and two antihistamines.

*Trademark for methaminodiazepoxide, Hoffmann-La Roche, Inc., Nutley, New Jersey.

MUCH OF psychiatric practice with chronically disturbed patients who seek help for their emotional ills is, of necessity, empirical. One or another modality, sometimes in combination, is employed to give the patient symptomatic relief as promptly as possible. The intensity of treatment is determined by the severity of incapacitation, but is also conditioned by patient co-operation which depends partly on the effectiveness of therapy. If the patient finds little relief in what seems to him a reasonable time, he is lost to further treatment until his symptoms become intolerable and he once again turns to the psychiatrist for help. The advent of psychiatric drugs has greatly facilitated the therapist's problem of sustaining treatment for a long enough period to enable him to get at the root of the ailment and achieve some measure of lasting improvement.

In common with most psychiatrists, the author does not look to *one* drug or even *several* as a panacea for neuroses and psychoses. Sharing the skepticism of some of my colleagues when Librium,* a new psychotherapeutic agent, was brought to my attention, I had reasonable doubts about its potential value. However, empiricism dictated the decision to put to clinical test a drug that offered promise of possible efficacy in the stubbornly unresponsive case.

This new drug had proved its remarkable taming effects in animals, much greater potency to relax tension and reduce fear than meprobamate, yet apparently did not interfere with alertness, or motor activity.[1] Its wide margin of safety was an-

*Trademark for methaminodiazepoxide, Hoffmann-La Roche, Inc., Nutley, New Jersey.

other determining factor in testing this new clinical tool. (Since the initiation of this clinical trial, several investigators have reported their results with this drug[2]).

Librium was therefore prescribed to a number of patients who previously received little or no relief of their mentally incapacitating symptomatology.

Patient Material

The group under study comprised fifty-one psychiatric patients (twenty-two male and twenty-nine female) ranging in age from twenty-one to seventy-three, 60 per cent of whom were between thirty-one and sixty. The diagnostic categories included reactive depression, anxiety depression, agitated depression, obsessive-compulsive reactions, schizophrenia, and schizoid personality. As can be seen from Table I the two largest diagnostic groups were reactive depressives and obsessive-compulsives, constituting nearly half of the total.

The duration of illness prior to treatment with Librium ranged from several months to twelve years, and the severity of the disturbances varied from a mild neurosis to manic depression. Previous modalities included psychotherapy, electro-shock therapy and the gamut of psychotropic drugs.

Patients were told that they were being given a new test drug which might or might not be more beneficial than previous medications. The dose varied from 25 mg. a day, usually at bedtime, to 25 mg. q.i.d. Approximately half of the patients (twenty-six) received the medication 25 mg. t.i.d., and one-fourth (thirteen) 50 mg. at bedtime. The duration of treatment varied from two to twenty weeks, and twenty-five received it for a period of two to four weeks.

Evaluation of results was based on subjective response reported by the patient, effect on behavior observed by the author, alleviation of symptoms sufficient to enable the patient to achieve a modicum of social adjustment, and improved interpersonal relationships. Since the psychiatric history and response to previous therapy had been well known to the author, any variation in response was readily perceptible; frequently the changes in behavior were recognized by the patient's family and friends.

Results

The over-all response to Librium and the results obtained in each category are summarized in Table I. (See preceding page.) Of the fifty-one patients, eleven had shown an excellent response, twenty-nine satisfactory, four were unimproved, and one patient who did not return after one week of the medication is included in the column designated as "questionable."

As can be seen from the table, the unsatisfactory results were obtained in one each of the manic depressive, schizoid personality, hypomanic, and anxiety-depressive groups. All patients in the obsessive-compulsive and reactive-depression categories and all but one of the patients with anxiety depression exhibited from good to excellent improvement.

The onset of effect of the drug was usually discernible both subjectively and behavioristically within a few days to a week, and most patients had gratifying results within two to four weeks, to the point where the medication could be reduced or discontinued. There were no ill effects even in patients who received the drug for as long as twenty weeks. One patient reported being drowsy on 75 mg. daily, and several who found that 50 mg. during the day made them sleepy, were improved when given the same dose at bedtime rather than during the day.

Frequently the patient had remarked that this medication "did more for them than any other tranquilizer." Patients who had been previously on meprobamate or other currently employed drugs expressed their satisfaction by saying that they "felt better on this drug than on any other." Its calming and relaxing effect provided the patient with sufficient support to derive greater benefit from psychotherapy than was otherwise possible.

A few typical case histories will serve to illustrate the type of response observed.

Report of Cases

Case 2.—Man, aged thirty-two, diagnosed as an obsessive-compulsive with symptoms dating back several months, has been on the medication, 25 mg. b.i.d. This patient had always been a perfectionist, but more recently began to worry so much over trifles as to interfere with both his work and sleep. He has been on the medication for 5 months and finds that it makes him "more relaxed" and he is enjoying life and his work in a way he has never before experienced. No untoward reactions or side effects were observed.

Case 6.—Woman, aged fifty-three. Diagnosis: reactive depression. Present illness was of three and one-half years' duration. This patient was started on 25 mg. t.i.d. and maintained on this dose for three months. She exhibited remarkably complete remission of symptoms, and

reported that she felt better than on any previous tranquilizer. When she was without medication for three days she became depressed, nervous, and upset. Reinstitution of the medication once more restored the calm she enjoyed on the drug. No side effects were noted.

Case 11.—Woman, aged sixty-six. Diagnosis: situational neurosis. When first seen the patient reported that her illness began about a year earlier when she moved to another town. Since then she had been unable to adjust to her new environment. Librium, 25 mg. t.i.d., was prescribed, but she found that this dosage-schedule made her drowsy. The dose was reduced to 25 mg. at 6 p.m. and at bedtime, which gave her a good night's sleep. She has been on this regimen for three months and has shown marked improvement in adjusting to the change which initially caused her disturbance.

Case 12.—Man, aged thirty. Diagnosis: anxiety neurosis. This patient gave a history of chronic anxiety and tension of twelve years' duration. Because of the chronicity of his condition, Librium was first prescribed at a dose of 25 mg. q.i.d. The patient has been on the medication for six months and is being maintained at a dosage schedule of 25 mg. morning and noon and 50 mg. h.s. He expressed a distinct preference for Librium over chlorpromazine which he had taken previously, and has shown an excellent response to Librium. He is relieved of his anxiety, thinks more clearly, and no longer suffers from a variety of fears he formerly experienced. He has also given up drinking which he often used previously "to calm my nerves," as he stated. He still has an occasional emotional set-back which requires supportive psychotherapy. In the six months of treatment he has shown no clinical side effects.

Case 15.—Woman, aged forty-seven. Diagnosis: manic depressive. This patient, a wife of a physician, had recurring episodes of hypomanic and manic phases for fifteen years. She was committed to a state hospital, but managed to escape from there. She refused to return home because she constantly clashed and quarreled with her husband and children. She was placed on Librium, 25 mg. q.i.d., and has been on the same dose for the past three months. She became less irritable, more cooperative, and regained insight. Her attitude towards her family changed for the better. She became interested again in her personal appearance. No adverse effects from the drug have been noted.

Comments and Conclusions

On the basis of fifty-one patients with a wide range of mental illness no attempt is here made to interpret the results in the terms of a definitive study. In reporting them, it is my purpose to convey my frankly unexpected finding that the response to Librium was indeed favorable. All but four patients who appeared not to have derived any help and one in whom the response was questionable, volunteered expressions such as "this drug is much better than anything prescribed to me before."

It should be pointed out that these patients suffered from a variety of psychiatric illness: obsessive-compulsion, reactive, anxiety and agitated depression, and several were schizophrenic or exhibited a typical schizoid personality. Regardless of the severity and duration of previous illness, alleviation of symptoms and improvement in behavior were unequivocal in the sizable number of patients benefited. The onset of improvement, in some instances within days, was sufficiently encouraging to the patient to want to continue with the treatment. Half of the patients experienced a most satisfactory therapeutic effect within two to four weeks on 25 mg. t.i.d., and are consistently maintaining this improvement.

Patients who have been on the medication for as long as twenty weeks have shown no adverse side effects. Drowsiness, reported by a few patients, was easily avoided by reducing the dosage to 10 mg. t.i.d. and 25 to 50 mg. at bedtime. This provided a good night's sleep without the need of additional nighttime sedation, and freed the patient from incapacitating fears and anxieties. The effects on behavior, social adjustment, and ability to face average stresses, as well as evidence of renewed interest in life, were remarkable. Those who required supportive psychotherapy were helped to accept more prolonged treatment.

On the basis of this study, Librium appears to me to be a most welcome, efficacious, and safe drug in the treatment of ambulatory patients in psychiatric office practice. It is my intention to continue to prescribe this drug in preference to other agents to relax the patient adjunctively to psychotherapy.

Invasive Hydatidiform Mole in the Urinary Bladder

The successful management of the rare hydatidiform mole is a rewarding achievement.

WILLIAM E. PRICE, M.D.
Minneapolis, Minnesota

THE URINARY bladder is rarely invaded by hydatidiform mole or chorionepithelioma. Recent pertinent literature contains no mention of vesical invasion although extensive metastases to other organs have frequently been cited. The following case is reported both because of its unusual features and to describe a method of conservative treatment.

The patient, a nineteen-year-old girl, was admitted to the hospital on July 21, 1958. A benign hydatidiform mole had been delivered at another hospital in May, 1958, followed by a dilatation and curettage. Intermittent bleeding ensued which was assumed to be vaginal in origin. Three weeks prior to admission, urinary obstruction developed which was relieved by passage of clotted blood. She was hospitalized after several recurrences of these symptoms.

Physical examination was normal, except for findings on pelvic examination done under general anesthesia at the time of cystoscopic examination. The cervix, uterine corpus and adnexae were normal. A movable, smooth, firm mass about two centimeters in diameter was palpated to the left of the midline in the region of the vesical trigone. No connection between the mass and the cervix could be felt.

The initial hemoglobin level was 7 grams per cent. The catheterized urinalysis showed many red blood cells. On July 25, the frog test for urinary chorionic gonadotropins was negative. The chest x-ray was normal. An excretory urogram demonstrated normal kidneys and a filling defect in the left side of the bladder.

On July 22, a dilatation and curettage was performed. Decidual reaction of endometrium was found without evidence of neoplasm or hydatidiform mole.

On July 23, cystourethroscopy showed a raised lesion on the left side of the trigone measuring about 1 centimeter in diameter covered with normal vesical mucosa except for a bleeding ulcerated area on the medial aspect. The left ureteral orifice was elevated on the lateral aspect of the tumor. The rest of the bladder and the urethra appeared normal. The lesion was biopsied with the resectoscope. Vigorous bleeding which followed was controlled by prolonged fulguration. Microscopically, the tumor consisted of blood clot, fibrin, leukocytes and fragments of degenerating chorionic

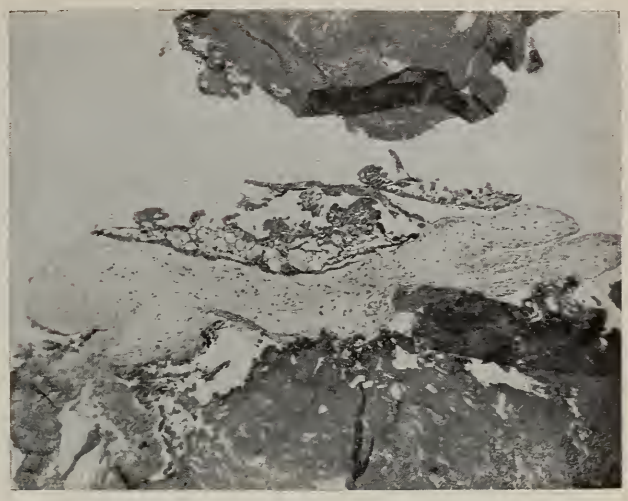

Fig. 1. Degenerating chorionic villus surrounded by blood clot, fibrin and leukocytes, low power field.

Presented at the meeting of the Minneapolis Academy of Medicine, October 20, 1958.

villi surrounded by trophoblastic cells (Fig. 1). This pattern was considered typical for a benign invasive hydatidiform mole, and the patient was discharged for further observation. Occasionally, metastatic nodules of an invasive hydatidiform mole will spontaneously disappear and a similar occurrence was believed possible with our patient. However, the close proximity of the markedly vascular tumor to the vesical lumen made operative intervention necessary before regression could occur. Hematuria and clot retention developed on July 29, requiring emergency cystoscopy, evacuation of clots, and fulguration of bleeders in the lesion. On July 31, the tumor was resected transurethrally. It consisted of a sharply demarcated cavity in the bladder wall filled with reddish-purple material. Several small finger-like processes which extended outward for a few millimeters from the main cavity were carefully destroyed. The left ureteral orifice was resected. Underlying bladder muscle fibers appeared clean, and bleeding was easily controlled. An inlying urethral catheter was removed twenty-four hours later; the patient voided satisfactorily and she was discharged on August 3. Microscopic examination of the excised tissue again showed invasive hydatidiform mole without evidence of chorionepithelioma.

The patient returned for a follow-up examination on October 13, 1958. She had no symptoms. Catheterized urinalysis showed 10 to 15 white blood cells per high power field. The urinary gonadotropin test was negative. No abnormalities were found on bimanual pelvic examination. Cystourethroscopy showed the resected region to be well healed except for an area of slough about one centimeter in diameter just above the vesical neck which grossly resembled post-resection inflammatory tissue. The left ureteral orifice was patent and well healed. The remaining portions of the bladder were normal. Further follow-up studies will be conducted at frequent intervals.

Discussion

An hydatidiform mole is a placental tumor whose development depends upon three factors: 1. Disappearance of fetal circulation due to death of the fetus, 2. edema of the villous connective tissue, and 3. nourishment of the functioning tropho-

blast by the maternal circulation. It occurs in approximately one in twenty-five hundred pregnancies and only about 2 per cent are followed by a chorionepithelioma (Novak and Novak).

Although the pathologic classification of hydatidiform mole has not been completely standardized, that of Novak and Novak is adequate for clinical purposes. Two subdivisions, benign and invasive, are recognized. The benign hydatidiform mole shows no destructive invasion of uterine tissue, varying degrees of trophoblastic activity and good preservation of chorionic villous pattern. The invasive hydatidiform mole, however, penetrates deeply into the myometrium and invades parauterine structures and vaginal tissues. Trophoblastic activity is more abnormal than in a benign mole, but the villous pattern is still preserved. In contrast, a chorionepithelioma is composed of sheets of invasive and destructive trophoblastic cells which have lost all semblance of chorionic villi. Novak and Novak state that regardless of the degree of trophoblastic overgrowth, the presence of choironic villi indicates a benign rather than malignant process.

Benign trophoblast exhibits many of the invasive qualities of carcinoma. During pregnancy, groups of trophoblastic cells and even chorionic villi are swept into the maternal circulation, and lodge and continue to grow in the lungs. These "physiologic metastases" normally disappear after termination of pregnancy, probably due to maternal defensive mechanisms. Hertig and Mansell state that roentgenologically demonstrable metastases from an invasive hydatidiform mole have been observed to disappear spontaneously. Evidently in the present case, molar villi were transported from the uterus to the vesical trigone through venous channels and continued to grow. Eventually, ulceration and hemorrhage occurred into the bladder lumen.

Clinicians agree that any patient suspected of having an invasive hydatidiform mole or chorionepithelioma should have frequent biologic assays of chorionic gonadotropins. Repeatedly positive tests, especially if the quantitative titre rises, constitutes an indication for hysterectomy. From this point, however, these two diseases differ markedly in their behavior. The patient with the invasive mole, judged either by histologic appearance of the trophoblast or presence of well formed chorionic villi, has an excellent chance of cure. Extensive metastatic lesions do not appear, and the few deaths that have occurred have been due to sepsis or uncontrolled intraperitoneal hemorrhage. On the other hand, a true chorionepithelioma, which is a carcinoma of villous epithelium, usually metastasizes to distant organs and death results from carcinomatosis.

Our patient presented the problem of management of a metastatic bleeding vesical tumor. She was only nineteen years old and in otherwise good health. The urinary chorionic gonadotropin test was negative, probably due to insufficient viable trophoblast being present at the time to give a positive result. Biopsy of the tumor showed a lesion of known benignancy, removal of which is usually followed by cure of the disease. Prompt therapy was necessary because of recurrent hemorrhages. We believed that transurethral resection of the bladder tumor was indicated rather than an open operation which would have undoubtedly resulted in cystectomy, panhysterectomy and urinary diversion to an isolated ileal loop. Close follow-up with repeated chorionic gonadotropin assays, chest x-rays, and cystoscopic examinations has been advised.

Summary

A nineteen-year-old patient with an invasive hydatidiform mole in the urinary bladder has been reported. A brief summary of clinical and pathological aspects of hydatidiform mole and chorionepithelioma has been presented. A possible method of pathogenesis in this instance has been discussed.

Additional Note

Since the presentation of this paper, the patient has been repeatedly examined, and no recurrence of molar tissue has been found. The latest examination was September 14, 1959. The chest x-ray was negative and cystoscopy showed the bladder well healed. Against medical advice, she has become pregnant and she is presently under the care of an obstetrician.

An Analysis of Treatment at Minneapolis General Hospital

CLAIRE J. STROBEL, M.D.
WALTER INDECK, M.D.
Minneapolis, Minnesota

Dr. Indeck is Clinical Assistant Professor of Orthopedics, University of Minnesota; Attending Orthopedic Surgeon, Minneapolis General Hospital.

TIBIAL fractures occur frequently and, since treatment must be individualized, each patient presents a specific problem in management. To provide insight into the problem of therapy, the patients admitted to the fracture and orthopedic service at the Minneapolis General Hospital with tibial fractures for the period January 1, 1955 to January 1, 1958, were analyzed. Records of 153 patients were reviewed. Twenty-two patients died soon after admission or early in the post-fracture period precluding follow-up information, and eleven transient patients were also lost to follow-up evaluation. Twenty-five of the patients with fractured tibias were children, and all of these patients had reduction by closed methods with uniformly good results.

Excluding the foregoing fifty-eight patients, a total of ninety-five patients comprised the study group. In eleven patients, bilateral fractures of the tibia were sustained; thus a total of 106 fractured tibias were analyzed.

Classification

Many types of classification exist with some based on the degree of injury, and others on the type of fracture or associated components of the fracture. The following division, however, appears to be a more useful grouping of these fractures; (1) tibial fractures with intact fibula, and (2) tibial fractures with a broken fibula. This separates injuries with grossly unstable fractures from those fractures having some element of remaining stability prior to treatment. Each category was subdivided into transverse, oblique, and comminuted types (Table I).

Therapy

Therapy has varied according to the presence or absence of fibular fractures in most cases. In our series of twenty cases of tibial fracture with intact fibula, none have been treated with internal fixation. Although this small number of combined cases may not be statistically significant, a practical aspect should be emphasized. These cases, including both simple and compound injuries have all been satisfactorily treated with long leg plaster immobilization. Some, however, have required remanipulation to correct minor angulations and displacements.

Therapy for the second broad category, fractured tibia with fractured fibula, has not been so uniform. The methods are divided into four groups:

TABLE II. RESULTS OF TREATMENT OF FRACTURED TIBIAS

Analysis Criteria	Fibula Intact			Fibula Broken					
				Transverse		Oblique		Comminuted	
	Transverse	Oblique	Comminuted	Internal Fixation	No Internal Fixation	Internal Fixation	No Internal Fixation	Internal Fixation	No Internal Fixation
Total limbs	6	9	5	7	23	11	16	10	19
Restricted knee	1	2	3	1	5	3	2	3	8
Restricted ankle	0	2	0	3	4	1	1	3	4
Shortening	0	2	1	3	10	1	2	3	6
Neuro-vascular	0	0	1	2	2	1	1	2	4
X-ray	1	3	2	2	5	3	7	2	4
Cosmetic	0	0	0	0	1	0	2	1	2
Symptomatic	2	1	2	3	4	2	2	5	8

A. Long leg plaster with or without the aid of anesthesia.

B. Traction by means of Kirschner wire fixation through os calcis and immobilization in a Baylor-

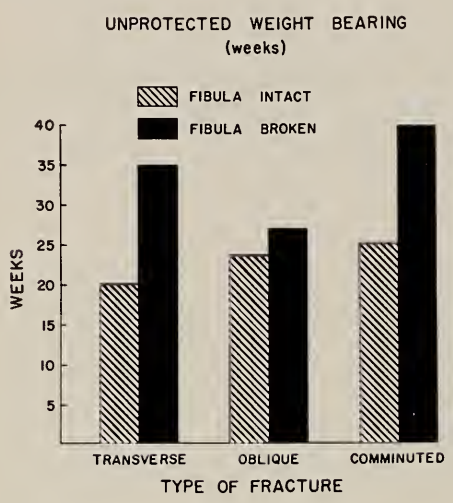

Fig. 1.

Braun frame. This type of fixation has been maintained for varying periods from three to five weeks with subsequent plaster immobilization until convalescence has been completed.

C. Extra-skeletal fixation utilizing transfixation wires through the fragments of the tibia and incorporated into the plaster cast.

D. Internal fixation: In simple fractures only one of the sixty-five cases had internal fixation prior to a trial manipulation and plaster immobilization. In several instances, the internal fixation technique was used following debridement of a compound wound; all areas involved were redraped prior to the fixation procedure. Internal fixation was also used as a delayed form of definitive therapy with bone grafts, bone chips, or a sliding type of graft.

Results

Success in treating fractures of the tibia depends on several criteria which are difficult to assess. In Table II, these fractures are analyzed according to seven different criteria which serve to provide a basis for expected end results.

Transverse Tibial Fractures

Six patients with transverse tibial fractures and intact fibulas did well. Thirty tibial fractures with the fibula broken were treated primarily with long leg plaster immobilization. Seven were treated with internal fixation. Table II summarizes these results and emphasizes the common occurrence of shortening. This did not appear to be symptomatic nor associated with significant disability.

Oblique Fractures

Table II summarizes the functional results of the oblique tibial fractures separated into those with

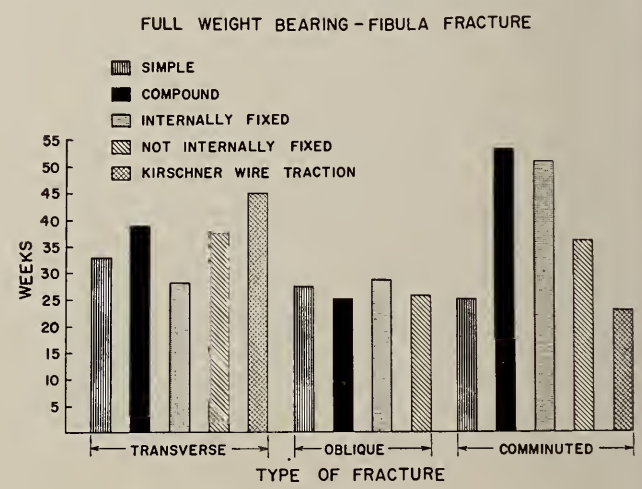

Fig. 2.

"fibula intact" and those with "fibula broken." Further subdivision into cases with and without internal fixation reveals: 1. Nine patients in the subgroup "intact fibula" who did not have internal

fixation; 2. Five patients with a combined fractured fibula were treated with plaster immobilization; 3. Internal fixation was used in eleven instances with a fibular fracture. Of note in the

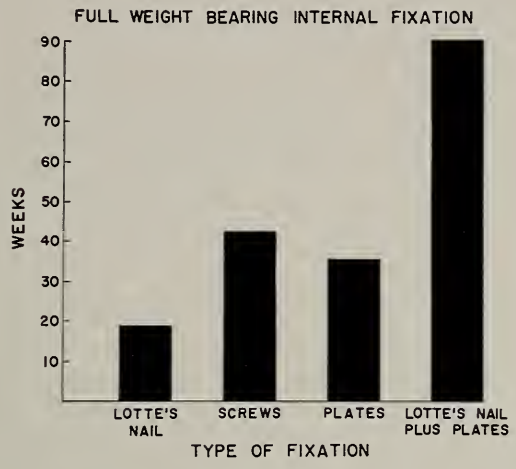

Fig. 3.

"oblique fracture with fibula intact" group is the possible association of altered mechanics of alignment and restricted motion.

In the "fractured fibula" subgroup those without internal fixation had a moderate frequency of x-ray malalignment as compared to those internally fixed. Symptomatically the results did not appear to be adversely affected by such malalignment.

Comminuted Tibial Fractures

Of twenty-nine patients with a combination of fractured tibia and fibula, ten were treated with internal fixation; nineteen were treated with manipulation and plaster, or skeletal traction. Attesting to the severity of this kind of injury is the high percentage of neurovascular sequelae resulting in this group as compared to the other types of fracture.

Weight Bearing

A comparison of similar types of tibial fractures in the two groups of internal fixation and plaster or traction are analyzed as to the time of full weight bearing without external support (Fig. 1).

UNPROTECTED WEIGHT BEARING

	Fibula Intact (average weeks)	*Fibula Broken* (average weeks)
Transverse fractures	20.3	36.0
Oblique fractures	23.6	26.6
Comminuted fractures	25.6	40.7

Several further breakdowns have been utilized in an attempt to crystallize impressions rather than to specifically outline objectives of treatment. As was mentioned previously, none of the twenty patients of tibial fractures with intact fibula were treated with internal fixation. Only one of those twenty fractures was compounded.

Further analysis of the fractures as to type and method of treatment is depicted in the following three tables and demonstrated in Figure 2.

TRANSVERSE FRACTURE, FIBULA BROKEN

	Number	*Average Weeks Full Weight*	
Simple	13	33	
Compound	17	39.1	(one non-union at 108 weeks)
Internally fixed	7	28.7	
Not internally fixed	23	38.2	(one fibrous union 80 weeks; one osteomyelitis and bone graft 104 weeks)
Kirschner wire traction	3	45.3	

OBLIQUE FRACTURE, FIBULA BROKEN

	Number	*Average Weeks Full Weight*	
Simple	20	27.3	
Compound	7	24.9	
Internally fixed	11	28.4	(3 non-union and grafts: 64, 52 and 48 weeks)
Not internally fixed	16	25.4	

COMMINUTED FRACTURES, FIBULA BROKEN

	Number	*Average Weeks Full Weight*	
Simple	13	25	
Compound	19	53.6	(2 non-union and bone grafts at 68 and 144 weeks)
Internally fixed	10	50.8	
Not internally fixed	19	35.4	(2 non-unions at 68 and 92 weeks)
Kirschner wire traction	3	22	

Twenty-eight limbs in all categories had internal fixation. The following is a summary of the various methods used and average time of healing (Fig. 3).

ALL CATEGORIES

	Number	*Average Weeks Full Weight*	
Lotte's nail	9	18.4	
Screws	8	41.9	(3 non-unions and bone grafts)
Plates	9	36.1	(1 osteomyelitis and 1 non-union and bone graft)
Lotte's nail plus plates	2	92	

Discussion

In transverse tibial fractures with the fibula intact the two symptomatic patients had unrelated osteomyelitis of the distal one-third of the femur with malunion of the hip on the same side; otherwise results were excellent. However, in those patients with a fracture of the fibula there was a significant number with shortening in those with, as well as without, internal fixation. There was a small number in each category with x-ray malalignment. This did not necessarily contribute to either a cosmetic or symptomatic abnormality.

Oblique fractures with the fibula intact show a fair amount of x-ray abnormality but again seemingly without symptoms. This x-ray picture of malalignment was also present in those with the fibula broken. It was most marked in those without internal fixation but not eliminated by internal fixation. Despite the x-ray picture these patients were generally asymptomatic.

Without a doubt the patients with the most residual symptomatology were those with comminuted fractures whether or not the fibula was intact. There was no apparent explanation for restriction of knee motion in those patients with the fibula intact. In the "fractured fibula" subgroup, the results did not differ significantly whether or not internal fixation was used. An added indication of the seriousness of trauma was the relatively high percentage of neurovascular impairment. In the group without internal fixation, there was a tendency for relatively more shortening.

Mechanical factors affected by minor degrees of angulation should be emphasized, for when the distal fragment is laterally displaced without angulation, there is a definite shift of the patient's weight bearing to the medial aspect of the ankle joint. This occurs even though a parallel line of weight bearing is created. When a valgus bow is created there is sometimes a prominence of the proximal fragment creating a significant cosmetic disability. In addition to this prominence, the weight bearing again is dropped medial to the ankle joint per se. With a varus bow, however, a tendency to overcome the subcutaneous prominence is present and also there is a tendency to restore weight bearing to a normal line.

Internal fixation in our institution reduced the incidence of x-ray malalignment. Shortening was still present in a significant number of cases so treated although usually anatomical results were obtained initially. This was the result of either subsequent procedures or intramedullary fixation with later shortening at the fracture site.

In regard to the time for various types of fractures to heal, there seems to be little choice between internal fixation or no internal fixation. Complications were not found to be any more frequent in the internally fixed group than in those treated with a long leg plaster only. The use of internal fixation in an attempt to improve immobilization and hasten early movements of both the knee and ankle has not proved effective. In the nine cases where a lotte's nail was used alone for internally fixing a fracture, the average time for full weight bearing was only 18.4 weeks. The average period of twenty-two weeks for complete healing of comminuted fractures with the fibula broken, and treated with Kirschner wire traction and subsequent long leg casting, was not expected.

Some difference was also noted between the two groups with, or without a fracture of the fibula. In those fractures in which the fibula was intact, all fractures healed with complete union. In the group in which the fibula was broken, two patients developed non-union and were subsequently treated with brace support; three amputations were necessary, two supracondylar in type and one below the knee.

Conclusions

This presentation has attempted to stress the basic methods of treatment, the average time of healing, and some comparison of results with the various types of fixation for tibial and fibular fractures.

As an outgrowth of our method of dividing patients with fractured tibias into those with, and those without, fractures fibulas, it is apparent that a more favorable outcome ensues in the case of a fractured tibia with the fibula remaining intact. Perhaps some thought should be given to stabilization of the fibula and an evaluation of this procedure as an adjunct to the other methods of treatment carried out.

Brain Injury Complicating Whiplash Injuries

A timely and provocative article, with medical legal implications.

SIDNEY K. SHAPIRO, M.D.
FERNANDO TORRES, M.D.
Minneapolis, Minnesota

From the Division of Neurology, University of Minnesota Medical School and Hospitals, Minneapolis, Minnesota.

BRAIN INJURY, which may be permanent, as a complication of whiplash injuries has not been documented in the literature. The presence of cerebral concussion in 22 to 62 per cent of cases has been reported but no detailed neurological electroencephalographic follow-up has been recorded. Abbott[1] reported in 62 per cent there is historical and symptomatic evidence of a cerebral concussion. Frankel[2] reports with respect to cerebral concussion that "the deceleration injury may in a large number of cases (22 to 30 per cent) produce concussion to the frontal and occipital areas of the brain. Torsional forces may likewise involve the brain stem, the area of the brain just above the spinal cord. The symptoms range from loss of consciousness for varied period to confusion, dizziness, or vertigo, headache, inability to concentrate and disorientation. Some of the symptoms have been found to last for several years."

The purpose of this publication is to present forty-seven patients with whiplash injuries in whom detailed neurological assessment and electroencephalographic studies were carried out. In the majority of the patients, repeated electroencephalograms were obtained at varying periods from the time of the accident. Twenty-one of the forty-seven patients showed moderate to marked abnormalities in the electroencephalogram, some of which have persisted for longer than eighteen months after the initial injury.

Material and Method

The forty-seven patients were carefully selected in that all patients in whom there was a suggestion that the head may have been struck were omitted in the study, and the forty-seven cases represent patients who sustained the usual whiplash type injury. None of the patients with the exception of one (case 46) had a history of any pre-existing neurological disorders. All the patients were involved in automobile accidents with the majority being struck from behind and the head and neck subjected to a hyperextension flexion movement. In some patients, the vehicle in which they were passengers was struck from the side with a lateral to and fro motion of the head and neck being sustained. All of the patients were examined by one of the authors (S.K.S.) and all the electroencephalograms were interpreted by co-author (F.T.). The patients were consecutive cases of whiplash injuries seen during the period of this study and all electroencephalograms were taken with the patient off of any medication which might influence the electroencephalogram.

In the evaluation of the electroencephalograms, the usual criteria for abnormality was employed. Theta activity was considered abnormal in adults below twenty-five years of age when it constituted more than 10 per cent of the occipital, parietal and posterior temporal frequencies, when it was paroxysmal or when it showed higher voltage than the background activity. Any amount of theta activity exceeding 5 per cent of the activity in any area of the head was considered abnormal in patients over twenty-five years of age. Obviously the percentages are only approximate and are used here in order to give a general idea of our criteria for evaluation. Spikes, high voltage sharp waves and delta activity were considered abnormal. The electroencephalograms were classified as normal, minimally abnormal, mildly abnormal, moderately abnormal and markedly abnormal.

Results

The results of the electroencephalographic studies are recorded in Table I. The ages in this group of patients range from age sixteen to age sixty-six. Three of the patients were in their teens, eleven patients in the age range from twenty to thirty, fourteen of the patients from thirty to forty, ten of the patients from forty to fifty, six of the patients from fifty to sixty and three of the patients from sixty to seventy. Twenty-one of the forty-seven patients had moderate to marked abnormalities in the electroencephalogram at some time in the period comprised by this study. It should be noted that the presence of a normal electroencephalogram in some instances was followed by the development of moderate abnormalities in four of the patients. The patients who showed moderate to marked abnormalities in the electroencephalogram at some time in the course of their illness showed the following breakdown with respect to the time they had been followed from the electroencephalographic standpoint. Twelve patients had been followed for less than twelve months, five patients from twelve to eighteen months, three patients from eighteen to twenty-four months and one patient after twenty-four months.

From the clinical standpoint, there was considerable variation in the clinical course. In some patients, the onset of the symptoms was delayed for several days to weeks and in a minority as long as several months after the time of the accident. In the patients in this study, there was no prolonged period of unconsciousness in any of the patients. Some had a momentary loss of consciousness lasting for a matter of seconds, being followed by a sensation of being bewildered, dazed, dull or stunned. Headaches not infrequently were complained of within a few minutes or hours after the accident but in some instances the onset of headaches occurred days to weeks after the initial accident. Some patients described a blinding sensation or a sensation as if the top of the head were being blown off at the time of the accident. Psychoneurotic type of symptomatology in the form of tenseness, nervousness, restlessness, sleeping difficulty and easy excitability was frequently encountered. Many of the patients complained of vertigo, recurrent headaches, difficulty concentrating in addition to the persistent symptomatology in the neck. Reflex abnormalities in the upper extremity were not infrequently encountered. These could be explained on the basis of the injuries in the neck. Not infrequently transient changes in the abdominal reflexes were noted and transient toe signs were demonstrated. In the majority of patients the abnormalities in the toe signs and the abdominal reflexes usually returned in a matter of days to weeks to normalcy. In fourteen of the patients mild or minimal changes occurred in the electroencephalogram. This type of abnormalities found in these fourteen patients is similar to those encountered in about 15 per cent of the normal population by various authors.[3-4] However, some of the abnormalities became focal and shifted from electroencephalogram to electroencephalogram and when correlated with the clinical picture, were probably significant in some of these patients.

Two of the patients in this series presented

features of unusual interest and a brief abstract of their case histories will be outlined.

Case History

Case 46.—This forty-seven-year-old patient was a front seat passenger in an automobile which was struck from behind by another automobile. The patient's head was thrown backwards and forwards. Immediately after the accident, the patient complained of pain in his neck and stated he became "pretty nervous." The headaches commenced about twenty-four hours later and the patient was awakened in the middle of the night with dizziness, nausea and vomiting. The next day the patient noted numbness of the left side of the face. He consulted his family physician and was admitted to hospital. Following admission to hospital, he continued to complain of severe neck pain, severe headaches, dizziness, numbness involving the left side of the face, disturbance of sensation involving the left eye and difficulty swallowing. When examined nine days after the initial accident, the patient had ptosis of the left upper lid, myosis on the left, decreased appreciation to pin prick over the complete sensory distribution of the left fifth cranial nerve, decreased corneal sensation on the left, mild involvement of heal to knee to toe test on the left, mild bilateral involvement of the finger to nose test, marked ataxia, mild decrease in appreciation of pin prick involving the right upper extremity, right side of the body and right lower leg, and dysarthria. At the time of the initial examination, he had moderate restriction of motion of the neck in all directions and moderate spasm of the paracervical musculature with moderate tenderness over the superior angle of the left scapula and over the long head of the biceps on the left. The left biceps reflex was absent while that on the right was present. The remainder of the reflex status was intact. The patient gave a history of previous neurological difficulty. At the age of five, he had had a fractured skull on the left side with penetration of the left side of the brain by a foreign object. Five years prior to his accident, he had had attacks in which the left leg lost strength and the left side of the face became numb and also at that time he had dizziness. Investigation at that time including angiography was negative and he had been free of symptoms for five years prior to the accident. In summary, the patient presented the clinical picture of a thrombosis of the posterior inferior cerebellar artery on the left. The patient has continued to have severe neurological residuals.

Case 45.—This patient was involved in the usual rear end type accident. She noted immediate sharp pain in the neck and was dazed and shaken up. In the evening of the accident, she awakened with severe pain in the neck and was unable to lift her head from the pillow because of the pain. Headaches were not noted until three weeks after the accident and they became of sufficient severity to waken the patient from her sleep. The neckaches and backaches persisted and the patient was hospitalized. While in hospital, some thirty-four days after the accident, the patient commenced to hallucinate. She stated that she overheard conversations about a patient being electrocuted. She became very disturbed, crying and expressing many paranoid ideas about the nursing staff and the conversations which they had been carrying on about her in the hall. It was necessary to move the patient to a locked unit. The psychosis responded to conservative treatment and cleared in a week. The patient has continued to have psychoneurotic symptomatology.

Discussion

The high incidence of brain injury as indicated by the moderate or marked abnormalities in the electroencephalogram may be in part due to the referred nature of the patients who were studied. If electroencephalograms are not obtained, no evidence will be forthcoming of the changes going

on in the brain in many instances and the doctor will be deprived of this valuable information. The brain injury may be purely mechanical. Due to the oscillations of the head and neck on a purely mechanical basis, injury can occur to the brain as it is brought into sudden contact with the skull. Another phenomenon in the production of brain injury is the acceleration or deceleration influences on the brain tissue as described in the experiments of Denny-Brown and Russell.[5] The third explanation for the brain damage encountered in this group of patients is on a circulatory basis due to a vascular insufficiency arising from involvement of the vertebral artery. Lewis and Coburn[6] have demonstrated by angiography constriction or occlusion of vertebral artery in patients in whom symptoms of rotatory ataxia, headaches, diplopia and unsteadiness of gait have persisted. The site of occlusion was at the second cervical level which is the point of greatest rotation of the head on the neck. Vertebral artery compression complicating whiplash injuries has become recognized as a complication of this type of injury.[2,7] Case 46 outlined above of posterior inferior cerebellar artery occlusion was probably on the basis of vascular insufficiency produced by involvement of the vertebral artery. This patient also serves to outline the fact that serious brain injury can be present in the presence of normal electroencephalogram. Patients who have pre-existing evidence of insufficiency of the vertebral-basilar artery systems or who have pathology in the vicinity of the vertebral artery can be expected to show a higher incidence of this type of complication following whiplash injuries. Frankel[2] noted that "arteriosclerosis, particularly of the vertebral artery, may make this artery more vulnerable to compression."

The majority of the authors who have written on the subject of whiplash injury recognize the presence of psychoneurosis as a complication of this injury. As an explanation of this psychoneurotic reaction, various theories have been advanced including: (1) hostility towards the driver of the other car is common and is often the basis of an emotional reaction; (2) frustration from an obvious or imagined lack of interest by the physician and accusation of malingering may produce a state of tension which protracts the period of pain and may lead to psychoneurotic reactions; (3) many patients develop a fear reaction over the knowledge of possible complications from injury to the spinal cord and brain.

It is of interest that injuries incurred in automobile accidents involving other areas of the body are not associated with the high incidence of psychoneurotic reactions encountered in the patients who have sustained whiplash injuries. For example, traumatic fractures of the lower extremities do not have the high frequency of psychoneurotic reactions and are infrequently seen in the office of a neuropsychiatrist. In view of the present study and the high incidence of abnormalities in the electroencephalogram, it is possible that in some patients at least the apparent psychoneurotic symptoms are organically determined and are symptomatic of the underlying brain injury. From the standpoint of treatment, the results of treatment of the psychoneurotic reactions in this group of patients who have persistent abnormalities in the electroencephalogram are less favorable than the group in which no abnormalities in the electroencephalogram are demonstrated. As outlined above Case 45 developed an acute psychosis following a whiplash injury in association with abnormalities in the electroencephalogram.

The majority of the patients in this study have been followed for too short a period of time to allow any final determination with respect to their brain injuries. It is hoped that this preliminary report will stimulate interest in this aspect of the problem of whiplash injuries so that additional data can be obtained. The combination of the clinical picture plus the electroencephalographic abnormalities in the four patients who have been followed longer than 18 months indicate that this group of patients has probably sustained permanent brain injury. The patient with occlusion of the posterior inferior cerebellar artery likewise has sustained permanent brain injury.

The Cell as a Mirror of Disease

JAMES W. REAGAN, M.D.
Cleveland, Ohio

Read at the annual meeting of the Minnesota State Medical Association, Duluth, Minnesota.

THE CELL is one of the most interesting structures in the field of science. To the best of our knowledge, it has existed on the earth for several million years. Through the process, which is referred to as evolution, the Master Builder made many improvements in the cell. He has achieved the ultimate in the cells of man.

Even by the standards of the machine age, the human cell is a very remarkable unit. In the human manufacturing plant, there is nothing to suggest an assembly line. Under normal conditions each cell is organized so that it can carry out its own job independently, whether this is the production of some essential material, the disposal of waste, or only muscular contraction. The body is so organized that there is an excess of workers; however, unemployment is unknown. Rest periods are thoughtfully provided for by the management.

The organization of the cell is such that a sit down strike is almost impossible under normal conditions. One cell cannot prevent its neighbor from carrying out an essential function. The economy of the cell is illustrated by the fact that even in death the cells of the epidermis continue to serve a useful function, the protection of the human organism.

While the cell has been in existence for several million years, we have studied it for only about three centuries. The word "cell" was given to us by Robert Hooke. He first used the term in describing the structure of cork. Under his primitive microscope he commented on the small compartments or pores which he visualized. He called them "cells" because he thought that they were hollow spaces. The spaces in plant tissue are somewhat different from the cells of the human. Among other things plant cells have very thick walls. This is necessary to provide support in structures which lack a separate skeletal system.

The cells in the higher mammals are rather complex structures. It might be interesting to consider some of their components so that we can better understand the changes which disease may bring about in the cells.

The cell is composed of a mass of protoplasm and a nucleus. The protoplasm surrounding the nucleus is referred to as the cytoplasm. At the periphery of the cell are two membranes. The outermost is the true cell membrane which is not well developed in human cells. It is well developed in plant cells. Inside this is the so-called false membrane which is invisible with the light microscope and is concerned with cell permeability. The cytoplasm is made up of a substance called hyaloplasm. Inside this there are certain formed structures which are referred to as the organelles —the little organs. These occur in all cells and include the mitochondria, the golgi apparatus, the cell center, and in plants the plastids. We are concerned with the nucleus whose chromatin combines with the basic dyes. This is surrounded by a nuclear membrane inside of which is the nuclear sap. This colorless material lies between the twisted filaments of chromatin. The chromatin also occurs in larger masses referred to as chromocenters. Some of these masses are acidophilic and represent nucleoli. These are some of the basic morphological features of the cell. The study of Cytology is by no means limited only to morphology but also includes a study of cellular chemistry and cellular function. Since morphology and function are so often related, it is almost impossible to deal with only one to the exclusion of the other.

We can apply this knowledge in certain instances to determine the origin of a cell. Cells of polygonal form are usually of epithelial origin. The cells have this form because they can be packed together without any wasted space. Very thin and wafer-like cells occur on the surface of a many layered or stratified squamous epithelium. On the basis of their size and shape, we know that the cells are from a stratified squamous epithelium which serves a protective function. In some of the lower animals, these cells actually overlap one another like plates of armor. In the center of the cells there are pyknotic nuclei which tell us that the cell is dead. Other cells are prismatic in form and have a nucleus situated at one pole. Such forms are characteristic of cells with a secreting function. Cell function and shape are well correlated in the nerve cells with their long processes which are ideally suited for conduction. Thus, by looking at the shape of a cell we may get information about its function and also its origin.

Other cells are modified in certain ways to provide a very special function. These modifications are collectively referred to as the products of functional adaptation. These include the fibrils which are observed in squamous cells which we know now to be related to keratinization. Also represented are the cuticle, the cilia, the brush border, the myofibrils, the neurofibrils, and a related group of inclusions. All of these may be modified in the diseased cell.

Many physicians still find it difficult to accept the fact that cells may depict what is going on in their tissues quite accurately. This is somewhat difficult to understand because the pathologist has been accumulating knowledge of the cellular changes of disease for over 100 years. While most of this time he has been dealing with the cellular changes in the tissues, he also has been dealing with isolated cells. Detailed studies of the cells in the blood are made in order to determine what is going on in the marrow. Similarly, the sediment of the urine is examined in order to gain information about what is going on in the kidneys. Only for a little over a decade have we become interested in the epithelial cells and the information they can give us. In some instances, it is actually easier to detect minor changes by studying cells than by studying their tissues. For example,

hormonal changes are often more readily appreciated in cell preparations from the vaginal pool than they are in the parent tissues.

Even minor abnormalities of the epithelium can

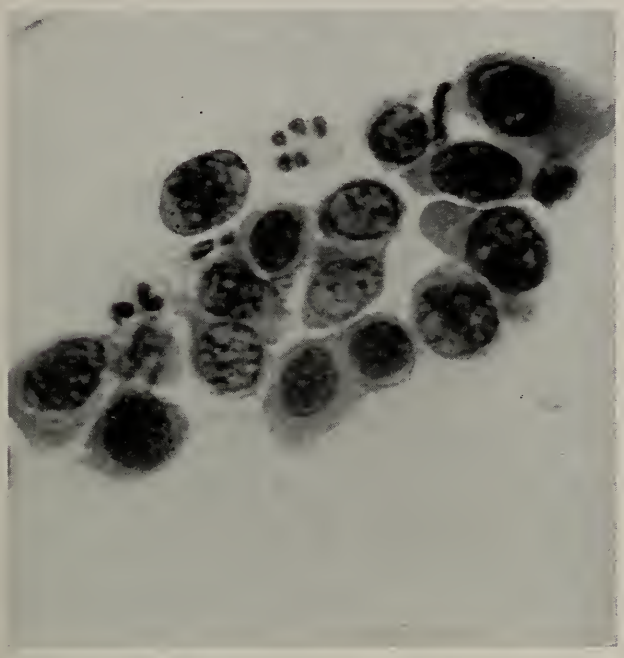

Fig. 3. Cells derived from a carcinoma *in situ* of the uterine cervix. × 500

be recognized by studying cells. Many different proliferative lesions can be demonstrated by examining the cells collected from critical areas.

The cells in Figure 1 are not human cells although they are thin wafer-like cells from a stratified squamous epithelium. They have very large nuclear masses and other structural changes which are associated with proliferating cells. They were observed in the vaginal pool of a mouse two weeks after a carcinogen-impregnated thread was inserted into the cervix. These cells are truly from a precancerous lesion because a keratinizing cancer was found four weeks later when the animal was sacrificed. On the basis of experimental work of this type there is definite proof that a significant surface change occurs in the cervix of the experimental animal prior to the development of cancer. By studying the cells which are shed, we can follow an animal through the stages of experimental carcinogenesis.

The cells depicted in Figure 2, which are from the human, have many of the features of the altered mouse cells. They have large nuclei and structural changes in the chromatin which are quite

significant. They may be associated with smaller red, orange, or yellow cells which have small dark pyknotic nuclei. These cells come from a change in the surface mucosa which we refer to as dysplasia

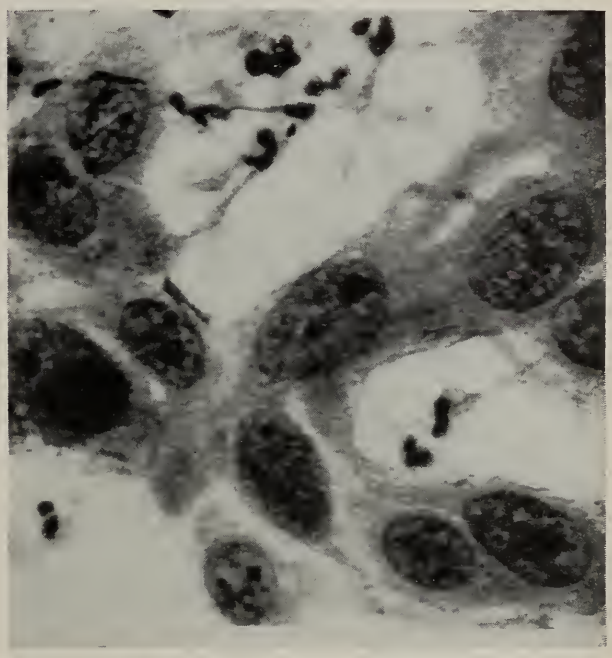

Fig. 4. Cells originating in a large cell non-keratinizing cancer of the uterine cervix. × 500

meaning malformation. The lesion occurs in the mucosa of the uterine cervix near the external cervical os and sometimes is observed over the portio vaginalis. About one in every 125 non pregnant women will have a change of this general type and the pregnant woman is even more apt to have such a lesion. Is this a precancerous lesion? Sometimes it does precede cancer. In many women this lesion disappears. This is the course of events in about 50 per cent of the women who are proved to have this change by biopsy. Biopsy in itself may remove the lesion in some cases. In about 35 per cent of the cases, it persists for varying periods of time and may recur even after it has been completely eradicated. In about 15 per cent of the cases, a more serious change is ultimately found. One might say that this is a potentially dangerous lesion.

The cells of Figure 3 are more omnious in their appearance. They are more immature and like primitive cells are usually associated with a high rate of cell division. The nuclei are relatively large in relation to the amount of cytoplasm. There are many people who believe that there is a high

likelihood for cancer to develop in women with these cells. They are from a change classified as carcinoma *in situ*. They were observed in a specimen taken from a thirty-two-year-old woman who consulted her physician because she was unable to conceive. The cervix was clean and a cellular specimen was collected as part of a routine examination. In our experience about four in every 1000 women will have this lesion.

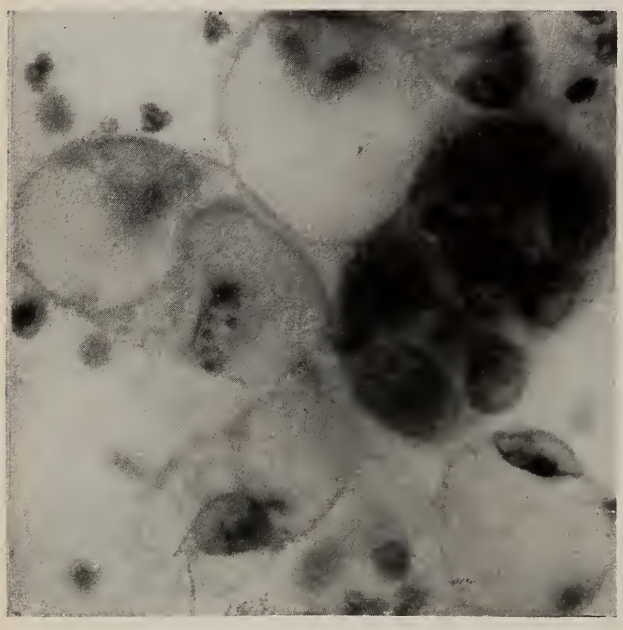

Fig. 5. Cells originating in adenocarcinoma primary in the uterus. × 500

The cells represented in Figure 4 are quite different. They are from the cervix of a sixty-four-year-old white woman who consulted her internist for a check up. Sixteen years ago she had a radical mastectomy for breast cancer and there was no evidence of recurrence. The cervix was described as being normal and nulliparous. A cellular specimen was taken as part of a complete pelvic examination. The cells were recognized as being from an epidermoid cancer of the uterine cervix. They lack the pleomorphism which characterizes the cells of keratinizing cancer and indicate the presence of a large cell non-keratinizing cancer. This form of cervical cancer has the best prognosis. The cancer which was found was a clinical stage I cancer of the cervix and this woman will survive two cancers in her lifetime.

The cells illustrated in Figure 5 are also cancer cells. They are different from the others that we have seen. They were found in the vaginal pool of a woman who went to her physician for a premarital examination. There was no history of abnormal bleeding and the cervix was described as normal. The large spaces represent secretion which indicates that the cells arose from a secreting epithelium and the parent lesion was an adenocarcinoma. Adenocarcinoma was found at D & C. Unfortunately, all of the adenocarcinomas do not shed their cells so readily. Endometrial aspiration increases the likelihood for demonstrating the cells of adenocarcinoma.

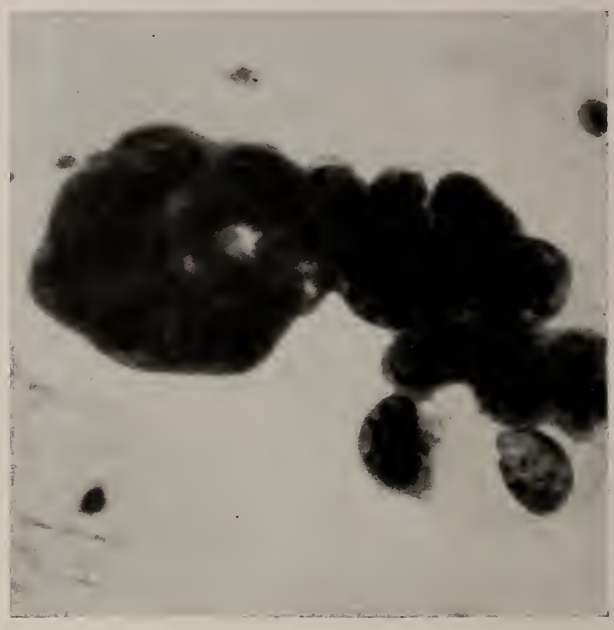

Fig. 6. Cells observed in aspirated material from the uterine cervix which are derived from adenocarcinoma primary in ovary. × 500

The cells in Figure 6 are also derived from adenocarcinoma and were found on a routine specimen in an eighty-four-year-old woman who complained of right lower quadrant pain and nausea. She had no post menopausal bleeding. These cells have some features which are suggestive of adenocarcinoma while other changes suggest that this is not a primary adenocarcinoma. These cells were reported as being from adenocarcinoma which was in all probability not primary in the uterus. She was ultimately proved to have a bilateral papillary adenocarcinoma of the ovary.

A knowledge of cells can be utilized in many different ways. One can search for evidence of tumor emboli in venous blood provide information about the radiosensitivity of a given cancer, and make other valuable contributions. Imprints of the tissues can be made to better study their cells.

Inclusions can be demonstrated in various cells. This includes large red inclusions of vaccinia and similar bodies observed in cytomegalic inclusion disease. Often it is desirable to establish the true sex of a patient as for example in Turner's syndrome. This can be determined by studying cells. The cells of the female have small planoconvex masses which are in relation to the nuclear membrane. They are called the female sex chromatin. When they are found in from 40 to 60 per cent of the cells scraped from the buccal mucosa there is evidence that the patient is female. They are not observed in cells of the male. There are many other applications for the study of cytology in the field of medicine.

For the most part, I have emphasized the cells related to the female genital tract, however, the approach is by no means limited to this site. It is used in many other areas with varying degrees of success.

I do not want to mislead you by considering only our accomplishments in dealing with cells without referring to our very real shortcomings. Even under optimal conditions cells are not always present in secretion from patients with cancer. The results are rather discouraging for adenocarcinoma of the corpus. Only about 50 to 80 per cent of the lesions will be detected by sampling the vaginal pool. It is possible to increase this accuracy only by aspirating directly from the uterine cavity. When this is done, 90 per cent of the adenocarcinomas can be demonstrated. The results in studying the uterine cervix are somewhat better. From 90 to 95 per cent of those women who have significant changes in the surface mucosa will have abnormal cells in specimens collected directly from the uterine cervix. While it is often possible to suggest on the basis of the cells the lesion which is present, this is not always the case. Our accuracy in recognizing the lesion referred to as carcinoma *in situ* was evaluated over a four-year period. Over this period of time, there were 137 consecutive cases of carcinoma *in situ* confirmed by histopathological study. Of these, 88 per cent were recognized as having cells which were compatible with carcinoma *in situ*. Conversely, however, of 127 consecutive cases which were studied cytologically and interpreted as being consistent with carcinoma *in situ* about 95 per cent were proved to be carcinoma *in situ* on histopathological study. Our shortcomings are by no means limited to a knowledge of cells. When we first became involved with the study of patients who had cellular evidence of abnormalities without a significant clinical lesion, the biopsy procedure was not as successful as we had once believed. Of 100 patients who were ultimately proved to have carcinoma *in situ* the initial biopsy confirmed the lesion in only 74 per cent of the cases. If it has done nothing else, cytology has indicated the need for improving biopsy technique.

This approach can be used effectively in many different ways. I am told that you in this state are planning a large scale screening program. In order to do this you will not purchase the latest book on cytology and get into business. It is much more complex than that. You must develop a whole team. The over-all success of the program depends on many individuals. The physician must be taught how to collect the specimen and in some cases this is the responsibility of a nurse or in institutions, a technical worker. If this is a large scale program, technicians must be trained to examine the material and screen out abnormal cases. In our own institutions, with a volume of about 30,000 cases or some 90,000 slides annually, it is physically impossible for me to examine each and every slide. I must depend on my very capable technical staff who incidentally do this job better than I could. The final decision must be made by the pathologist who must have experience in dealing with cells. Where an abnormality is found and biopsy is to be done, this must be individualized in each case because biopsy done for the purpose of demonstrating a lesion which is not apparent on inspection is quite different from biopsy in a woman who has an apparent lesion. Finally, the pathologist must be prepared to study the specimen comprehensively in many cases in order to detect some of these early lesions. According to vital statistics there will be about 26,000 new cases of carcinoma of the cervix this year and 12,000 women will die of cancer of the uterine cervix. Already there is evidence to suggest that this death rate can be and actually is being reduced by cancer detection programs and the procedures which are now available to us.

Since the cell mirrors the parent tissues from which it arises, a study of cells can be used to advantage in gaining knowledge about various critical areas in the human which are accessible. This is a very useful adjunct in diagnosis. It is not in any sense a substitute for good clinical judgement or for biopsy where indicated.

Remarks on Aging

Extension of remarks made at the annual meetings of the Northern and Southern Minnesota Medical Associations in Duluth and Rochester, September 11 and 14, 1959, respectively.

LEO A. NASH, M.D.
Saint Paul, Minnesota

IT IS NOW ESTIMATED that there are over 15 million people in the United States over sixty-five years of age which is approximately 10 per cent of the population. At the present time, this figure is growing at twice the rate of the normal population increase. Planning for solutions of the problems of aging is everybody's business. We as physicians have a tremendous responsibility in this matter since eventually the medical care of the aged becomes the primary consideration in dealing with this large segment of society. What factors have contributed to a longer life span and created these problems associated with aging? We may list some of these factors herewith.

Contributing Factors to a Longer Life Span

1. *Medical.*—Earlier diagnosis, the use of antibiotics and chemotherapy, improved surgical procedures and anesthesia and other forms of therapy certainly have contributed to longer life.

2. *Standard of Living.*—As a society, we have higher dietary and housing standards than several generations ago. These coupled with improved public health programs and better working conditions have contributed to this increase in the numbers of the aged.

3. *Urbanization, Economic Shift, and Change in Pattern of Family Life.*—While socio-economic in nature, these things have added much to the creation of the "problems of the aging population."

4. *Compulsory Retirement on Basis of Age Alone.*—While this is not directly related to the medical aspects of aging, it concerns us as citizens.

5. *Cost of Total Health Care.*—A higher incidence of illness is present in the older age group than in the rest of the population. With increasing services given in hospitals and nursing homes, associated with higher labor costs generally, the cost of institutional care has risen faster than the cost of living. It is held that physicians' fees as such have not risen similarly. The doctor's fee constitutes only a fraction of the total cost of illness, however this is rarely pointed out and we as physicians are identified almost always with the cost of total medical and health care.

What kinds of people and what groups are actively working in the field of aging? Some are:

1. *Scientists.*—These are sociologists, economists, psychologists, insurance actuaries, and medical scientists who are studying aging objectively according to their own disciplines.

2. *Dedicated Groups.*—These represent church and fraternal organizations, unions, professional groups and responsible individuals. Some two hundred nationally recognized organizations have been listed in this effort.

3. *Professional Social Workers.*—These include governmental and industrial representatives in the general field of welfare at various levels.

4. *Others.*—In this group we find politicians, representatives of reactionary groups, "do-gooders," and even those with a guilt complex. It has been stated that the problem of aging is essentially a political one, and will be solved by the people. We may for the present disregard the fact that in certain areas the electorate consists of as high as 25 per cent of the voters, but this has its implications.

Activities of Organized Medicine

The American Medical Association has recognized aging formally for only a few years with the establishment of a Committee on Aging, but was previously identified with the problem through the activities of other committees. It might be pointed out at this time that the term "geriatrics" has been replaced by the more inclusive term "aging" in reference to this subject.

Currently, the American Medical Association is very active in the field and sponsored a national planning meeting in 1958, co-sponsored a joint meeting with the American Dental Association, The American Hospital Association, and the American Nursing Home Association with

the establishment of a Joint Council in 1959. The American Medical Association is now sponsoring regional meetings in various parts of the country, the most recent being held in Minneapolis in October, 1959, with representation from Minnesota, Wisconsin, Iowa, North Dakota, and South Dakota. In 1958, the American Medical Association published a six point program for older citizens reproduced herewith.

AMA Six-point Program for Older Citizens

1. Stimulation of a realistic attitude toward aging.
2. Promotion of health maintenance programs and wider use of restorative and rehabilitative services.
3. Extension of effective methods of financing health care for persons over 65.
4. Expansion of skilled personnel training programs and improvement of medical and related facilities for older people.
5. Amplification of medical and socio-economic research in problems of the aging.
6. Leadership and co-operation in community activities for senior citizens.

Governmental Activities in the Field of Aging

Governmental activities in the field of aging are those at local, state, and federal levels. In Minnesota, Governor Freeman has sponsored two Governor's Conferences on Aging, in 1956 and 1959 and has established a Governor's Council on Aging with a full time consultant. The Minnesota State Medical Association is represented on the Council.

Federal Activities in the Field of Aging

These activities are implemented chiefly through the Department of Health, Education, and Welfare. In September, 1958, the 85th Congress passed Public Law Number 85-908 establishing a White House Conference on Aging to be held January, 1961. The purpose of the conference is to define the needs of the aged and to recommend proper legislation. At the present time, information is fragmentary as to the needs of the aged, derived often from isolated sources. Further at the federal level, the Senate Subcommittee on Problems of the Aged and Aging has held hearings to determine the nature of the problems in this area.

Activities in Minnesota in the Field of Aging

In addition to those previously mentioned, a rather well planned effort is being made in Minnesota at the present time in preparation for the White House Conference. This effort is implemented through the Governor's Council on Aging. A Health Committee has been established with subcommittees on rehabilitation, nursing homes, home care and financing. A five county survey on the needs of the aged in central Minnesota is underway. A study of farmers retired on Social Security, directed by a representative from the Department of Sociology of the University of Minnesota will be made. The American Association of University Women will survey some ten urban centers with a house to house canvass to determine the needs of the aged. These data will be published in a Fact Book, the cost of which will be underwritten by the Wilder Charities of Saint Paul. Regional meetings will be held and all of the information gathered will be presented at the Third Governor's Conference on Aging in the fall of 1960 for further classification and this information and these data and proper recommendations will then be presented by the Minnesota delegates to the White House Conference in January, 1961.

The Individual Physician and Aging

It is urged that every medical society, either county or regional, general or special and every other organization including groups such as hospital medical staffs incorporate in their programs discussions on the problems of aging to alert the individual physician to this which has been called Medicine's Number One Problem. Undeniably, whenever the problems of aging are discussed, the areas of housing, recreation, hobbies, employment, mental health, social adjustment and all else pale before the problem of medical and health care costs. We as physicians are identified with these costs and it is incumbent upon us to think about these matters individually and to discuss them collectively so that we as a group may make some positive suggestions to be presented eventually to the White House Conference in 1961. We hope that the Committee on Aging of the Minnesota State Medical Association together with other committees can formulate some positive ideas reflecting the thinking of the entire profession in Minnesota to achieve this aim.

Case Report

Fig. 1. Petechial hemorrhages on the arm and chest of a six-year-old girl. The purpura was caused by a hypersensitivity to Penicillin G.

Nonthrombopenic Purpura Associated with Penicillin Hypersensitivity

WARREN J. WARWICK, M.D.

Minneapolis, Minnesota

PENICILLIN was introduced to medicine in 1943 for the treatment of infectious diseases. Soon thereafter reports of various penicillin toxicities began to appear in the literature. Sporadically cases were reported of purpura associated with penicillin therapy.[1-23] Twenty-six such cases have been reported: one of thrombocytopenic purpura, the rest of the nonthrombocytopenic varieties, usually of the Henoch-Schönlein type, including one death associated with penicillin therapy and purpura. The following case is much milder than those previously reported in that the patient presented only purpura, and that later an immediate and delayed penicillin hypersensitivity was demonstrated.

Review of the Literature

The Henoch-Schönlein type of purpura caused by penicillin was described by Anderson[1] who, in 1947, reported the case of a thirty-seven-year-old man with transient swelling of the joints and subcutaneous tissues, toxic nephritis, and intestinal purpura following a second treatment with intramuscular penicillin. Mirabel[2] described angioneurotic edema, acute nephritis, and an urticarial skin rash with papules, petechiae, and ecchymosis, in a sixty-year-old man, starting about a month after his only treatment with intramuscular penicillin. Spring's[3] patient was a fifty-three-year-old man who developed abdominal pain, swollen joints, myalgia, nephritis, azotemia, the nephrotic syndrome, and a vesicular and macular purpuric skin rash after a single injection of penicillin. Piraino[4] presented the case report of a three-year-old with abdominal pain, nausea and vomiting, tarry stools, joint pains, urticaria, and a purpuric rash, after her third treatment with penicillin for otitis media. Jensen[5] found arthralgia, abdominal pain, melena, and a petechial rash in a twenty-seven-year-old man who received a single course of intramuscular penicillin. Casser's[6] case was an eight-month-old girl who had small purpuric lesions, with abdominal pain and brown emesis, following her second treatment with penicillin. Hadida's[7] eleven-year-old patient had an ulcerative pyoderma which had not responded to twenty days' treatment with tetracycline. The pyoderma cleared after four intramuscular doses of penicillin, but the patient developed arthritis, a petechial purpura, abdominal pain, vomiting, and intestinal hemorrhage. Van der Hoeden[8] cared for three patients who had intestinal bleeding after injections of penicillin.

(Turn to Page 485)

The work reported in this paper was supported, in part, by grants from Minnesota Heart Association and American Heart Association.

Dr. Warwick is Instructor in the Department of Pediatrics, University of Minnesota.

The first was a fifty-two-year-old man who during his fourth treatment with intramuscular penicillin developed an urticarial, petechial skin eruption and hemorrhagic feces. The second was a fifty-eight-year-old man with bronchitis whose asthma was activated and who developed bloody stools after receiving intramuscular penicillin. The third patient was a twenty-eight-year-old woman who received intramuscular penicillin for a dental abscess and who passed bloody, diarrheal stools within a few hours.

Other purpuric manifestations of penicillin sensitivity have also been reported. Price[9] noted petechiae and later urticaria, arthralgia, and fever in a Canadian Army driver while he was receiving a series of injections of intramuscular penicillin. Hinman, Warner and Li[10] described an urticarial and scarlatiniform rash which cleared, and then a severe, generalized, ecchymotic eruption in an eighty-five-year-old man after a course of intramuscular penicillin. Derzavis and Beinstein[11] recorded progressive changes from an erythematous, maculopapular to a hemorrhagic, vesicular to a gangrenous, ulcerative eruption in a fifty-six-year-old man, following several intramuscular injections of penicillin in oil and beeswax. Criep and Cohen[12] recorded three cases. Their first was a fifty-six-year-old man who had arthralgia, urticaria, angioneurotic edema, and purpura of the eyelids, lips and hands five days after inhalations of penicillin dust. Their second case was a fifty-one-year-old man with angioneurotic edema of the eyelids and hands, and generalized urticaria and purpura, following a third injection of penicillin in ten days' time. Their third case was a fifty-two-year-old man who had arthralgia, pruritus, angioneurotic edema of the eyelids, hands and feet, generalized urticaria and purpura, following his first treatment with intramuscular penicillin. Goetze[13] reported two cases. The first was in a fifty-six-year-old man who developed nonthrombopenic purpura after his second course of intramuscular penicillin. The other was a forty-year-old man who developed nonthrombopenic purpura after a course of intramuscular penicillin. MacGibbon[14] observed a twenty-eight-year-old man with nonthrombopenic purpura, nausea, diarrhea, pallor, dizzy feeling, apprehension, and malaise within a few hours after his first penicillin injection. Samitz et al[15] treated a forty-four-year-old man for subacute bacterial endocarditis with Penicillin G injections for sixteen days when petechiae developed on his arms, legs, and neck. These spread to his face and hands the following day, and then produced a hemorrhagic bullous eruption. He recovered when the Penicillin G was stopped and he later took Penicillin O without difficulty. Richter's patient,[16] a twenty-five-year-old man with chronic pyoderma, also developed a bullous eruption with hemorrhagic necrosis of the skin while receiving a course of intramuscular injections of penicillin. Stahl[17] found the development of large, bilateral hematomas in the thighs of a thirty-nine-year-old woman on simultaneous therapy with penicillin and Tromexan®. Témime and Carlin[18] gave their twenty-eight-year-old patient penicillin and terramycin for an acute pharyngitis—she had had penicillin and streptomycin the preceding year—with the formation of disseminated petechiae and a bullous skin eruption with hemorrhagic necrosis in some areas. Two intramuscular injections of penicillin, given for a cough, produced generalized petechiae and a bullous hemorrhagic skin eruption in the patient of Laugier and Renard.[19]

One case of thrombocytopenic purpura caused by penicillin has been reported. Krusius' patient,[20] a sixty-nine-year-old man, was chronically ill with cirrhosis, cystitis, and pyelonephritis. During one year, he had three courses of intramuscular penicillin. During the third treatment, he developed petechiae, ecchymosis, and epistaxis, associated with a platelet count of 14,000.

There are at least two reports of isolated prolonged bleeding time associated with penicillin therapy. Pillsbury, Steiger, and Gibson's patient,[21] a thirty-one-year-old woman, developed urticaria, laryngeal edema, and asthma while receiving post-surgical prophylactic penicillin. This was controlled with Benadryl® and Pyribenzamine.® Seventeen days later, she developed ecchymosis, vaginal bleeding, tarry stools, coffee-ground emesis, hematuria, bleeding gums, and a prolonged bleeding time. Frick, Wise, and Varco[22] reported the case of a forty-nine-year-old woman who had a hemorrhagic diathesis and a prolonged bleeding time, but with normal platelets and plasma coagulation factors, while receiving penicillin following surgery.

There has been only one case of a fatal purpuric type of reaction associated with penicillin therapy. Yeh's patient,[23] a thirty-six-year-old man, received intramuscular penicillin for an illness manifested by fever and swelling of the arms. After two days of treatment, he developed a hemorrhagic pur-

pura with peripheral gangrene, and despite blood transfusions and injections of vitamin K and ascorbic acid, he died two days later.

The case here reported of a purpuric penicillin reaction differs from the above because there were no complicating factors or other symptoms.

Case Report

This six-year-old white girl was first taken to a physician on March 17, 1958 because of malaise, fever, and enlarged posterior cervical lymph nodes. She was treated with Sulfose®, one tablet every six hours, and intramuscular procaine penicillin, 300,000 units daily for three days. She was then given tablets, 250,000 units of Penicillin G four times a day with the sulfa preparation. This was continued until April 4, 1958, when she developed a fever of 102 degrees and a generalized purpuric rash which was predominantly over her body and extremities, but not on her face. She was taken to the emergency room of the DeWitt Army Hospital, Fort Belvoir, Virginia. The physician in the emergency room discontinued medication with the penicillin and Sulfose® and gave instead aureomycin, 250 mg. three times a day. When next seen on April 7, 1958, the purpuric rash had faded from the body, was still prominent on the arms, and had spread to the face. Her temperature had returned to normal.

In the past, she had uncomplicated rubella, rubeola, and mumps, in addition to several upper respiratory infections, for some of which she had received penicillin.

Notable physical findings were a flushed face covered with numerous petechial hemorrhages. Petechiae were also present on her arms and chest (Fig. 1). Her white blood count was 4,500, with 50 per cent neutrophils, 49 per cent lymphocytes, and 1 per cent monocytes. The hemoglobin was 12.3 gm. per cent, and the platelet count 202,000. The bleeding time was 155 seconds, and the Lee-White coagulation time was ten minutes, thirty seconds. The urinalysis showed no abnormalities. A throat culture revealed no significant microorganisms, except for two colonies of Beta hemolytic streptococci (typing was not done), and a single blood culture was sterile. A Rumpel-Leede test was strongly positive.

On April 7, 1958, the white blood count was 3,450, with 42 per cent neutrophils and 58 per cent lymphocytes. No pathogens were found on throat culture.

On April 8, 1958 the white blood count was 3,300, with 24 per cent neutrophils, 66 per cent lymphocytes, 8 per cent monocytes, 1 per cent eosinophils, and 1 per cent basophils. Stool culture showed no enteric pathogens, but another throat culture grew out 2+ Beta hemolytic streptococci. The platelet count was 187,000, and the clot retraction was normal. The petechiae had almost completely disappeared.

A heterophile agglutination was positive in 1:112 dilution, but as a differential absorption was not done, the test was repeated. This time the heterophile agglutination was positive 1:56. The absorption with guinea pig kidney cells showed no titer, but absorption with beef red blood cells showed a residual titer of 1:25. The total protein was 8 gm. per cent. The electrophoretic pattern revealed 49.7 per cent albumin, 8.5 per cent $Alpha_1$ globulin, 9.5 per cent $Alpha_2$ globulin, 12.9 per cent Beta globulin, and 23.1 per cent Gamma globulin. An antistreptolysin-O titer was up to 833 Todd units. No C-reactive protein was found. The bone marrow was normal.

At the time of writing, fifteen months after the illness, the patient has continued in good health with no recurrent purpura.

In February, 1959, she was given an intradermal skin test with 20,000 units of aqueous penicillin after the method of Welch and Rostenberg.[24,25] Within a few minutes, she demonstrated an immediate hypersensitivity response. There was a two cm. area of redness, surrounding a one cm. edematous area which was surrounded by a 5 mm. blanched area. A single pseudopod extended from the central raised area to the edge of the erythema. Forty-eight hours later, there was a three mm. area of necrosis at the site of the injection with a surrounding one cm. area of erythema (Fig. 2).

Discussion

This is a case of nonthrombopenic purpura, not of the Henoch-Schönlein type. The causes of this type of purpura include certain acute infectious and chronic diseases, certain skin diseases, various forms of dysglobulinemia, avitaminosis C and P, some allergic processes, and a direct toxic action or an idiosyncrasy to certain chemical and animal agents.[26] Several of these diseases are implicated as possible causes in the case history: streptococcal infection, infectious mononucleosis, hyperglobulinemia, and the administered sulfa and penicillin.

The possibility that this could have been due to a streptococcal infection bears careful consideration. Andrews[27] described three cases of purpura and one case of Henoch-Schönlein purpura which occurred during an epidemic of scarlet fever. Each patient had symptoms of streptococcal infection, and from three of them Lancefield group A Beta hemolytic streptococci were isolated on throat culture. All had antistreptolysin-O titers which rose to very high levels. They also reported a case of Henoch-Schönlein purpura in a fifty-six-year-old woman with an ASO titer of 525 Todd units. Gairdner[28] also implicated the streptococcus as being important in the genesis of Henoch-Schönlein purpura. Eleven of twelve patients had a hemolytic streptococcus recovered from their throat during the active stage or later, with or without a definite infection. Unfortunately, he did not group the streptococci or make antibody determinations. One of his cases developed rheumatic carditis. However, Bywaters and associates[29]

found neither increased incidence of raised antistreptolysin-O titers nor an increased mean antistreptolysin-O titer when they compared a group of 19 children with Henoch-Schönlein purpura with forty similar non-rheumatic children. These contrasted sharply with the significant increase in both findings in 107 cases of acute rheumatic fever, all of which were under twelve years of age. Ten of their 28 cases of Henoch-Schönlein purpura had been given chemotherapy or penicillin lozenges for treatment of an upper respiratory tract infection before the onset of the purpura.

In this case, the elevated antistreptolysin-O titer is evidence of a recent streptococcal infection. Because the patient had received treatment with 1,000,000 units of oral penicillin and one gram of sulfonamides daily for two weeks, and then tetracycline 125 mg. four times daily for three days, it is unlikely that the streptococcus isolated was from Lancefield group A, as these streptococci are uniformly penicillin-sensitive. Unfortunately, this organism was not typed, so that this point cannot be established. That this purpura might have been the result of streptococcal disease remains a remote, but unlikely, possibility.

Mononucleosis was thought of as the cause for the purpura when a titer of 1:112 was obtained initially. The persistent absence of Downey type leukocytoid lymphocytes and the differential absorption indicating normal serum heterophile rule out this possibility.

The slight elevation of the total protein and the gamma globulin fraction suggested that hyperglobulinemic purpura was to be considered. The purpura, however, has not relapsed, did not appear chiefly on the legs, and it left no residual pigmented spots,[30] so her illness is distinct from that entity.

Hyperglobulinemia with macroglobulinemia[31] may occur and cause a severe, fatal, purpuric disease in elderly persons. The patient's age and the complete recovery rule this out, even though ultracentrifuge studies were not obtained.

The purpura in this case, therefore, appears to be the result of an acquired idiosyncrasy to one of her medications, the sulfonamides or penicillin.

The sulfonamides were eliminated because the recorded cases of purpura caused by sulfonamide, that is, the cases of Geiger's[32] and Bolton and Young's[33] have been of the thrombocytopenic variety, and because she has since taken Sulfose® without adverse effects.

Penicillin was implicated because of its known ability to cause nonthrombopenic purpura. The later demonstration of both immediate and delayed type hypersensitivity to 20,000 units of aqueous penicillin provide further confirmatory evidence.

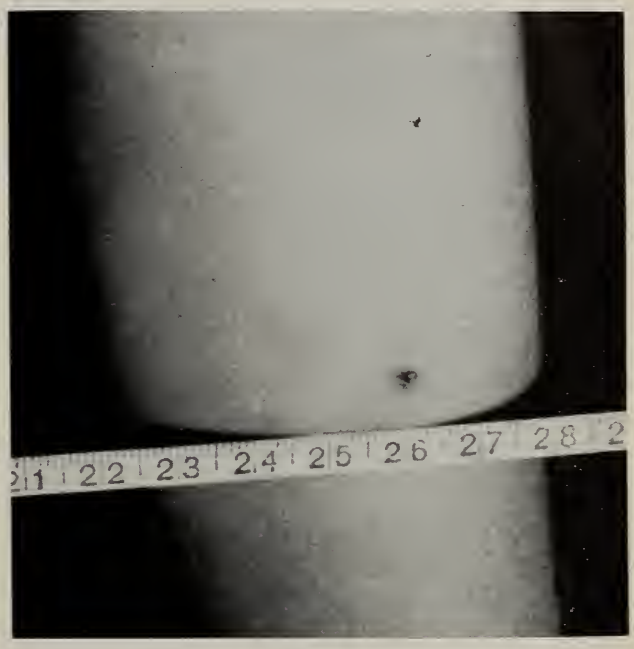

Fig. 2. Delayed sensitivity reaction forty-eight hours after the intradermal injection of 20,000 units of aqueous Penicillin G. There is a 3 millimeter area of necrosis, surrounded by a 1 centimeter area of erythema.

THE REVISED CURRICULUM

The revised curriculum for the junior and senior years of the University of Minnesota Medical School began on June 20, 1960, after a year and a half of planning. Exciting the revision was the need to eliminate the fragmentation and compartmentalization of the students' schedules which often enervated his senior year and reduced him to a passive, sometimes uninterested, bystander.

Dr. James B. Carey, Jr., was appointed curriculum coordinator, and with the heads of the medical school teaching departments formed a curriculum committee on January 15, 1959. On November 11, 1959, the recommendations were accepted for the revised medical school curriculum.

In the new curriculum the junior and senior years are a single period of twenty-four months, the junior-senior biennium. These two years are divided into blocks of time of which a total of twelve months is spent on in-patient clerkships, much as is done at present. There are also three months of elective time, three months free time, and a six month assignment to the Comprehensive Clinic Program to complete the twenty-four months.

These are referred to as block time assignments since the clerkships are interrupted by only one lecture a day, 4:00 to 5:00 p.m. These lectures are given the year around to the combined third and fourth year classes.

Another feature of the curriculum is the increased flexibility in the course of the individual student. Not only is there no rigid sequence of the required clerkships but the elective quarter permits some individualization of training. The student may use his elective time for course work, research, clerkship, or externship in any of the medical or pre-medical sciences and hospital services at the University or other medical schools. The block of free time may be used for vacation, but it is expected that many students will use that time to obtain a continuous six months for independent study.

The Comprehensive Clinic encompasses one-fourth of the students' last two years of medical school, and is the biggest of the curriculum changes. This part of the program is supported by a grant from the Louis W. and Maud Hill Family Foundation and is directed by Dr. Richard Magraw or Assistant Dean of the Medical School. The main objectives of the Comprehensive Clinic Program are to give the student doctor an active role in the care of out-patients similar to that given interns, to re-emphasize the patient as the unit of teaching and practice, and to improve patient care by making it possible for each patient to have a specific doctor who will integrate all of his care in the clinic until the patient is discharged or admitted to the hospital.

New patients admitted to the Adult Medical and the Pediatrics Clinic and private patients in North Clinic are assigned to the student doctors.

The student doctor, whenever feasible, initiates and completes the diagnostic and therapeutic aspects of his patient's care. The supervising staff physician will be the consultant, observer and teacher of the student at all times. When further consultation is required at a subspecialty clinic, the student is present as the patient's doctor and presents the patient to the consultant. Thus, in most situations, the student is the doctor to whom the patient looks for direction. It is expected that this more realistic and practical emphasis, the stimulus of responsibility, and the continuity of patient care will result in greater learning and will provide opportunity for the student to synthesize his knowledge of medical science and the phenomena of illness.

In order to promote this program, the Out-Patient Department has adopted a complete appointment system. Patients with appointments will be seen at the time of those appointments. Those without appointments will also be seen but in their turn. Of course, care of emergency cases has not been changed. Renewed emphasis has been given to the consultative role of the Out-Patient Clinics in returning patients promptly to the referring physician with detailed reports of diagnosis, treatment, and recommendation for care. Continued medical care is being given to those patients who require diagnostic or therapeutic facilities that are not generally available or who are participating in a clinical research program.

THE WHITE HOUSE CONFERENCE ON AGING

Public awareness of the challenges and problems of our aging population has produced a number of diverse actions, the most significant and far reaching of which is the passage of Public Law 85-908 by Congress creating the White House Conference on Aging to be held in January, 1961. This act has compelled thousands of our citizens nationally to study, evaluate and consider the status of older people in this country and in turn report these findings at the White House Conference and make recommendations to the President which then will be made available to the public. Regardless of the genesis of this awareness, be it humanitarian, political or scientifically objective, the Conference should serve a real purpose. Short of a national election or a poll, it should reflect the thinking of the people. Delegates to the Conference will be chosen by state governors on the basis of population. Some 1,740 delegates will be selected this way together with 660 representing national voluntary organizations and some 400 others will be designated to attend by the Secretary of Health, Education and Welfare. Minnesota will have 36 delegates in the group of 1,740. The format of the Conference will center about twenty topics related to the field of aging; of these twenty, some eleven have either direct or indirect medical connotations. This appears to be proper distribution of topics since the most compelling problems of the aged have some medical implications or at least a health overlay coupled with costs. The presentation and study of these costs and the related problems as they apply to the aged have been described as the Number 1 Domestic Issue of the present time. The White House Conference of 1961 appears to be the most important large public gathering in the foreseeable future.

Nevertheless, critics and detractors of the intent and consequences of the White House Conference are something less than enthusiastic or optimistic about it. Why is this so? Cursory consideration of the issue reveals some answers promptly and patently. Since the electorate now consists of some 25 per cent of voters over sixty-five years of age and some 50 per cent over forty-five years of age, the issue thus is basically political. Further, the apathy manifest in certain areas toward the White House Conference stems from the real fact that information to date regarding the problems of the aged and aging has been fragmentary, emotionally inspired and not scientifically correct in terms of the real needs of this population group. It is thus feared by some that the data to be presented at the White House Conference will thus be emotionally tinctured if not politically tainted.

In Minnesota, elaborate studies are being made in anticipation of the White House Conference which will be made public on completion by the implementing agency, the Governor's Citizen Council on Aging. This Council is composed of some twenty-six individuals with representation from business, labor, education, medical and paramedical groups, clubs, voluntary organizations, public employees and officials, the latter group embracing the "professionals" in the field of aging and welfare. These individuals serve voluntarily. The severest critics have labeled some of them liberal extremists. This writer has not found this to be the case. Contrarily, they are kind, sympathetic, and both dedicated and orderly in their own disciplines. Is this not the thinking of the physician?

The ultimate selection of delegates to the White House Conference from Minnesota will be made by Governor Freeman; the actual selection will be made by a committee of the Governor's Citizens Council on Aging. We have scanty knowledge about the activities in other parts of the country, and we do not know if special interests will be served in the selection of delegates from other states, but it is our thinking that the philosophy of the people of Minnesota will be represented at the White House Conference. Further, in the interests of Minnesota, if there are any doubts of the twenty section chairmen at the White House Conference, four are from our state or natives thereof. Dr. Leonard W. Larson will chair the critical section on Health and Medical Care with other section chairmen including Dr. John E. Anderson of the Department of Psychology of the University, Mr. Walter E. Nelson of Minneapolis, and Mrs. Charles Hymes, President, National Council of Jewish Women, and the wife of a physician. Minnesota, Hail to Thee!

Leo A. Nash, M.D.

THE WORK EVALUATION UNIT

The Minnesota Heart Association has long realized the importance of the problem of employment of the cardiac patient in industry. The association felt the urgency of suggesting solutions to this problem and was certain it could be helpful in

this field. Extensive studies both in the field and in the literature indicated the vital role a work evaluation unit could play as at least a partial solution to this need. Several units of the forty-eight now operating nationally were visited to see first hand how they were conducted and what results they were obtaining.

These observations revealed that the units were effective in solving some of the problems of the cardiac patient and his work status.

The Minnesota Heart Association felt a project established on a pilot basis would be a worthwhile community service and professional education project. Consultations were held with the Heart Committee of the Minnesota State Medical Association and after considerable study this committee, and finally the State Medical Association itself, approved the project.

A nine-thousand-dollar annual budget was set up by our association to partially support the unit. The Kenny Institute generously provided us with space without charge, and offered some laboratory services at a minimal cost. Without the enthusiastic support of the fine staff at Kenny, it would have been far more difficult to establish and operate such a unit.

The Unit was established in March, 1959, and has operated on nearly every Wednesday since. Patients are accepted only on referral from private physicians. Various other professional disciplines are necessary for successful operation. Besides secretarial help it requires a cardiologist, a medical social worker, and a vocational counsellor, as well as other physicians.

The patient is interviewed by the social workers who determines the social background of the individual, his previous occupations, family problems, work motivation, and necessity for work. A general knowledge of his financial status is of considerable importance in determining both the need and motivation for employment. The vocational connsellor carefully interviews the patient as to his previous occupation, the work requirements of the job, and emotional pressures. He also determines the fitness of the employee to adapt himself to other vocations should that be necessary or desirable if the findings of the evaluation suggest the patient should change his vocation. The vocational counsellor's knowledge of the various agencies and the possibilities of assistance from them are very helpful. The counsellor's acquaintance with industries in the area willing to assist in the program of employing the handicapped individuals is often invaluable.

The patient then undergoes the medical evaluation. A complete history is taken by the physician. This includes not only the immediate cardiac history but also the past history of other medical conditions. An attempt is made to give an accurate evaluation of the history of the original attack and subsequent symptoms. The patient's symptoms, as they relate to ordinary activities of life such as dressing, bathing, walking, eating, are carefully recorded.

A complete physical examination is then performed. A chest x-ray, hemoglobin, and urinalysis is obtained, and a standard 12-lead electrocardiogram is taken. If the examining physician believes a standard exercise test is not contraindicated, this test is performed, using if possible the Double Masters two-step technique. If the patient develops pain or dyspnea during the test, the exercise is stopped and the usual post-exercise electrocardiogram is obtained. All the preceding information is then assembled and presented to the conference which consists of the director of the unit, one or more staff physicians, visiting internists, the social worker and the vocational counsellor.

In the discussion, the combined opinion and judgment of these individuals is obtained concerning the work potential of the patient. If he can perform the exercise test without symptoms or EKG changes, it is presumed that he can perform this amount of work (8.5 calories per minute) for a period of three minutes. The caloric requirements of most vocations are well known. Most of the usual industrial jobs require about 3.5 calories per minute with peak loads up to 4.5 calories per minute. Obviously, an individual who can perform 8.5 calories without symptoms or evidences of damage to his myocardium should have very little difficulty with these ordinary vocations.

However, if the patient cannot perform the standard exercise test, we know his work potential is below 8.5 calories per minute. These patients must at times be further evaluated. Dr. Frederick Kottke, Professor and Head of the Department of Physical Medicine at the University of Minnesota, has been helpful in this field. He has a workshop where individuals can be tested at various levels of activity and this has proved very useful to us. Following the testing in the laboratory, we are able very accurately to ascertain the level of safe activities for the patient. At the present time, we are

arranging with the Workshop at the Kenny Institute so that these evaluations can be made under our direction because the precise measurements available from Dr. Kottke necessarily must be limited to a small number of persons. These simulated work experiments are carried on for several hours thus giving the unit some idea as to the endurance of the patient.

With all this evidence in hand, the conference is then able to give an unbiased opinion about the work potential of the patient. We then frequently find the individual is able to resume his former employment. Under other circumstances, it will be necessary to have him seek a lighter form of work, for which he may need not only assistance in finding such a position but may need vocational training in order to be able to perform this new type of work. Certain patients will be found to be unable to perform any gainful employment, and this fact is then stated.

The Minnesota Heart Association has established a fee of $50 for this examination. No patient has been refused the services of the unit if he is unable to pay all or even part of the fee. The difference between fee collected and costs is underwritten as a public service by the Minnesota Heart Association.

The value of the service to the patient is considerable. Sometimes all the patient needs is the reassurance he receives by passing the examination. This alone will sometimes suffice to get him back into the industry. The fact that the determination is made by a group rather than by an individual lends reinforcement to the opinion already expressed by the private physician. The fact that the statement is unbiased makes it easier for the patient to deal with employers and others.

The value to the physician is two-fold. In the first place, he receives the benefit of a group opinion regarding the patient. Secondly, instead of being placed in the oft-time embarrassing position of being forced to state his position to the patient, he now can defer to the judgment of an objective impartial panel.

The community gains in several ways. Many cardiac patients can be returned to gainful employment instead of being the recipient of public support. The Cleveland Unit which has spent $100,000 on its unit in ten years has found that the wages earned by the patients returned to work during that time amounts to 17 million dollars. The unbiased opinion rendered by the group has made the employers more anxious to employ these individuals. Industry is usually willing to cooperate but wants security in the placing of the individuals. This group opinion gives them the assurance that if the cardiac is placed in accordance with the recommendations made, the industry will not be placed in an embarrassing position either from the standpoint of compensation or sickness and accident benefits. Labor which seeks to obtain employment for its members can also use this unbiased opinion to guide them. Certainly, labor does not wish to place the cardiac patient in a position dangerous to himself or to his colleagues. With this approach, labor finds itself in a better position to help its cardiac members.

It would seem that services afforded by the Work Evaluation Unit present a new approach to a long-standing and difficult problem and can be used to advantage by various groups of individuals. Wholehearted support of the Unit by these groups will do much to help the cardiac patient. We strongly urge that those interested contact the Cardiac Work Evaluation Unit, 1800 Chicago Avenue, Minneapolis, Minnesota. The telephone number is FEderal 9-9115.

A. C. Kerkhof, M.D.
President
Minnesota Heart Association

THE WATER SUPPLY AND SEWAGE DISPOSAL PROBLEM IN SUBURBIA

The extensive use of private wells and septic tanks in the suburban areas of the state is creating a serious threat to public health. A great many wells have not been constructed with care to prevent the entrance of surface water, nor located a safe distance away from cesspools, septic tanks and sewers, and thus have been contaminated directly with sewage.

Important, however, as proper location and construction are from the standpoint of health, these factors alone do not guarantee permanent safety in the use of individual water supply and sewerage systems in highly developed areas. The practice of drawing the water supply of the community from the ground beneath the community by means of numerous private wells, and returning the water to the ground in the form of sewage, obviously presents a condition which sooner or later may result in recirculation. In the early stages of this trouble, low concentrations of sewage chemi-

cals such as laundry detergents are found in the water. Later, these disturbances become more frequent and acute and the sewage chemicals may be accompanied by sewage bacteria. From time to time a great variety of toxic materials are disposed of deliberately or accidentally to sewerage systems. For this reason sewage contamination of the ground water is dangerous even in the early stages before bacteriological evidence is found. In one suburban community in the Twin City area, a survey has shown that approximately 1760 (60 per cent) of the individual water supplies in the community are affected in this way. Surveys in thirty-four other suburban communities have had equally startling results.

Since the effects of contaminated wells are usually limited to minor intestinal ailments, such as diarrhea, it is difficult to say how widespread contamination of individual water supplies is, but because such upsets are common and because they are usually caused by contaminated food or drink, it can be assumed that polluted wells are frequently at fault. There are numerous instances on record in which illness has been spread in this manner.

A great many septic tank systems also have been poorly designed and have been installed where conditions of soil and ground water are such that there is little if any possibility of successful performance. Failure of these systems results in pollution of the surface of the ground, causes noxious odors, and interferes with the operation of the entire plumbing system.

The health significance of sewage contamination of the ground surface is obvious. The avenues and vectors by means of which the organisms of those diseases transmitted through the fecal-oral route may be conveyed from exposed sewage to articles of food or drink can be enumerated endlessly. No one living in a community where private sewage disposal system nuisances are prevalent has the means of protecting himself against these hazards. One of the most startling examples of the difficulty that can arise from failure and abuses in the use of individual sewage disposal systems involves a small suburban community north of St. Paul. Of the 1400 residential establishments in that community, 800 have failed to the point where sewage is backing up into the plumbing fixtures and overflowing onto the surface of the ground.

The philosophy that developed communities can be served indefinitely by individual water supplies and sewerage systems is false. Such systems are basically intended for use in rural areas. The only proper permanent solution to the water supply and sewage disposal problem of built-up areas is the installation of central water supplies and sewage collection and disposal systems. In some cases this can be accomplished by an individual community independently. In other cases joint action by a number of communities may be necessary. Joint action, however, is sometimes hindered by a snarl of legal and philosophical obstacles. Appropriate legislation and a great amount of education will be necessary before many of these obstacles can be overcome.

F. L. Woodward

UNION OFFICIALS HAUNTED BY WORKERS' GROWING DEMAND FOR FREEDOM

A spectre is haunting the Jimmy Hoffas and the Walter Reuthers of this Nation—the spectre of right-to-work laws. They would like to believe their own oratory when they call it a "dead" issue, yet their still-strenuous efforts against right to work belie the fact that it is dead.

AFL-CIO President George Meany, for example, who confidently pronounced the funeral oration for voluntary unionism after the 1958 elections, told the delegates to the AFL-CIO convention in September, 1959, that the growing interest in state right-to-work laws is one of the three critical problems facing union officials.

What is the reason for this revival of pro-right-to-work sentiment?

Right to work continues to be a dominant issue simply because it protects a basic principle of human freedom, and human liberty cannot be continuously suppressed. Every tyrant throughout the course of history has experienced the relentless insurrection of human beings striving for freedom from oppression. The Big Labor bosses today are perched precariously astride that same relentless rebellion which takes shape in the demand that union membership, like membership in every other private organization, be made voluntary instead of compulsory.

The term "right to work" means that a person has the right to work for a living without being forced to join a labor union. Right-to-work laws are not against unions—but are only concerned with leaving the decision of whether or not to

join such unions to the individual workers. The motto of the National Right to Work Committee, therefore, is "Americans must have the right, but not be compelled to join labor unions."

Most present-day union bosses would take away that freedom of choice by compelling workers to join a union through "union shop" contracts. Since state right-to-work laws outlaw the so-called union shop, these laws naturally are the targets of the bosses' wrath.

A moment of reflection will show, however, that advocates of right to work stand in the American tradition of freedom. For throughout our Nation's history, its citizens have battled for freedom of choice, and against any form of compulsory membership in private organizations.

Take the early days of our Republic—the colonial period. At that time, the group known as "dissenters" led the fight for religious freedom, and for abolition of compulsory support of the established churches which existed in nine of the original colonies.

Three requirements existed for the citizens of those nine states. They were: (1) to attend the official church; (2) to pay taxes for support of the church; and (3) to adhere to the official church ideology. But resistance to this compulsion was so extensive, that by the time of the American Revolution only financial support through taxation was required of those citizens not members of the established churches.

The issue of such compulsory taxation resulted, in 1786, in the struggle over the Virginia Statue for Religious Freedom. It is worthy of note that the great orator, Patrick Henry, argued that since religion promotes happiness and prosperity for all, everyone should be compelled to contribute to the church. He advanced much the same "free rider" argument as today's union bosses, who claim that since unions allegedly help all the workers, every worker should be compelled to pay dues.

This reasoning was rejected by the Virginia House of Delegates, and eventually by all the other states. Instead, the states followed the reasoning of the Statute's author, Thomas Jefferson, who declared that "to compel a man to furnish contributions of money for the propagation of opinions which he disbelieves and abhors is sinful and tyrannical." The Statute for Religious Freedom was passed.

The issue of freedom of association again became a prominent issue at the beginning of the 20th Century, when the rise of Big Business really began. At that time, many employers forced their employees to sign "yellow dog" contracts, which stipulated that the worker could not belong to the newly-organized unions if he wished to get and keep a job. This was such a clear violation of the worker's right to organize to improve his working conditions, *and of his freedom of association,* that many states, and eventually Congress rightfully outlawed the "yellow dog" contract. Once again, Americans stood firm on the principle of the individual's right to belong or not to belong to private associations.

* * *

With this historical perspective, let us look at the present controversy over Right to Work laws. We find the situation to be the reverse of that which existed at the beginning of the century. Today the unions are strong and powerful, protected by both state and Federal law. Unfortunately, their professional leaders have fallen for the same philosophy of compulsion which first characterized the leaders of Big Business. They want to be given the right to force workers into their unions, and to pay dues which are used for politics and other purposes far removed from the issue of collective bargaining.

This changed outlook among the union bosses is best revealed by comparing the philosophy of Samuel Gompers, the founder and first president of the American Federation of Labor, with that of George Meany, the current president of the combined AFL-CIO. Gompers, at the 1926 convention of the AFL, told his delegates: "I want to urge devotion to the fundamentals of human liberty—the principles of voluntarism. No lasting gain has ever come from compulsion. If we seek to force, we but tear apart that which, united, is invincible." And it is "capital punishment," Gompers said, "if a union expels a member and he is deprived of a livelihood."

Contrast this with the philosophy of George Meany, as expressed just this last year: "I see no harm in power . . . if it is power for good." How many dictators throughout history have attempted to justify their power by such reasoning! Many Americans, however, would not agree with Mr. Meany's conception of what is "good." Nor would the majority of our Nation's lawmakers, who passed the Landrum-Griffin labor bill in the last session of Congress over the loud protests of Mr. Meany and other union bosses.

Or contrast Samuel Gomper's philosophy with that of Al Hayes, president of the International Association of Machinists, who upheld the expulsion of two California Machinists members for publicly supporting Right To Work in the 1958 campaign. An IAM member, says Mr. Hayes, is not entitled "to openly denounce the considered position of the labor movement and his own union organization without the possibility of losing his rights to retain his standing as an IAM member." In effect, he says, the freedom of speech guaranteed by the Constitution does not apply to you as a union member.

Such concentration of power in the hands of a union boss like Al Hayes could be tolerated if his union were completely voluntary, and only those who agree with him belonged. But over half of the Machinists' contracts have "union shop" provisions, so that protesting members find their jobs cut off by expulsion from the union.

There is one way, and one way only, to curtail such tyranny of union bosses over their members: enactment of Right To Work laws in every state of the Union. Under such laws, the worker who disagrees with the policy of his union, and who finds that there is no remedy within the union, can sever his membership without losing his job and his means of livelihood. And the union boss, under such a form of voluntary membership, would soon realize that he must pay attention to the needs and opinions of his members if he is to retain power.

Like most great movements, the right-to-work movement has been making steady, if not spectacular progress since the first state law banning compulsory unionism was passed in 1944. Today, nineteen states have right-to-work laws, and citizens groups are working actively for such legislation in several additional states. An informed public, given the facts, will eventually put an end to compulsory unionism in the United States. Freedom of association is the American ideal and the American practice, and it is for that reason that right-to-work will inevitably win.

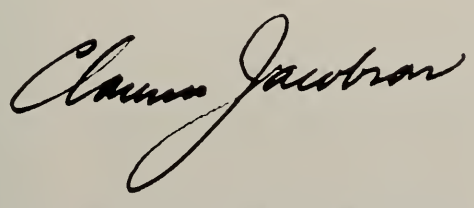
President's Letter

IT WAS A GOOD MEETING



The prevailing consensus has been that our Association enjoyed one of its outstanding meetings this year at Rochester. The Zumbro Valley Medical Society put forth their best efforts and succeeded in making the event a significant one. They deserve and are extended the thanks and appreciation of the profession.

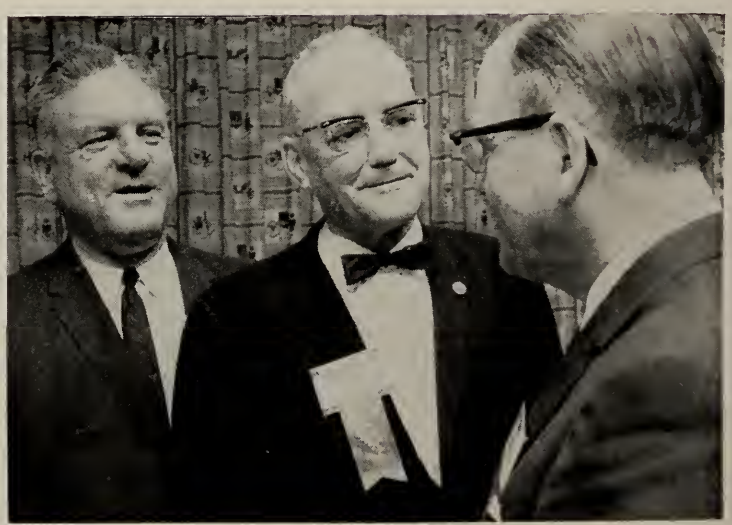
It was indeed a well executed and informative scientific program, covering the latest advances applicable to everyday practice. We hope that members will continue to suggest ways and means to the state office for further improvement of our programs. This should be done before the Committee on Scientific Assembly meets in October. This committee constantly seeks to meet the prevailing demand for a program which will maintain a high scientific standard and at the same time answer the need of the doctor in his practice.

The House of Delegates seemed better informed on the many vital issues placed before them from the various reference committees. A spirit of mature insight and restraint in discussing controversial problems appeared to prevail throughout the entire meeting. Matters at hand were resolved without rancor or needless discussion. Intelligent decisions can only be made on resolutions received early by the state office. However, in fairness to everyone, an arbitrary deadline has not been advisable. The consequences are nevertheless apparent. Deliberation by each delegate on the content of each resolution is obviously desirable in order to render a fair decision.

Committee reports represent conscientious work and reflect the unity in medicine's efforts to maintain a profession free to act in the best interest of people entrusted to our care. Our opposition to the expedient measures before Congress were manifested in action during this session. The messages sent to our Congressmen and Senators were the opinions of the individual doctor and no doubt gave them food for thought before embarking upon a reckless course of action. Appealing to intelligent appraisal appears to have had a salutary effect.

State Association meetings of the quality we have enjoyed can only be continued in the environment of freedom. Minnesota physicians have continued to be informed regarding the many devious efforts to divert them from their avowed purpose. Truly they have responded with a determined will to prevail.

President, *Minnesota State Medical Association*



Minnesota State Medical Association

DELEGATES MEET—The House of Delegates of the Minnesota State Medical Association is shown in session in the Royal Coach Room of the Kahler Hotel. Presiding over the meeting at right is Dr. Haddon Carryer, Rochester, speaker of the House.

SPEAKERS—Rep. Thomas B. Curtis (R-Mo.), a key figure in the House Ways and Means Committee, left, was a featured speaker May 23 at the House of Delegates banquet. Dr. Haddon M. Carryer, right, of Rochester, is speaker of the House of Delegates.

NEW OFFICERS—Among officers of the Minnesota State Medical Association elected at the closing session of the House of Delegates are, left to right: Dr. J. M. Stickney, Rochester, delegate to the American Medical Association; and Dr. C. L. Oppegaard, Crookston, president-elect. Dr. Clarence Jacobson, Chisholm, at right, is current president who retires December 31.

. . . 107th Annual Meeting Highlights

A total of 2,538 persons, including 1,209 physicians, were registered for the 107th Annual Meeting of the Minnesota State Medical Association, May 23, 24 and 25, 1960, in Rochester. Scientific sessions were held in the Mayo Civic Auditorium and the Business sessions of the House of Delegates were held in the Kahler Hotel.

A number of significant actions and items of business were considered by the House of Delegates.

Blue Shield Resolutions Considered

There were seven resolutions from county societies and specialty groups, all dealing with some phase of the operation of Blue Shield in Minnesota or with the handling of professional services of doctors in the hospitals. Two of these received consideration and action on the floor of the House. The other five were referred for consideration by the Council.

Dr. C. L. Oppegaard, Chairman of the Council, reported to the House of Delegates that the Council and the Board of Directors of Blue Shield are very close to agreement on the points of difference between the two groups. Delegates were told that the Blue Shield Board has agreed that representation on the corporate body for every county medical society in the state is essential.

Still to be determined is the method to be used for the selection of the incorporators. It was suggested that Blue Shield take immediate steps to appoint a special committee of the Board to develop and submit proposals to the Council of the Association. Doctor Oppegaard told the Delegates there was good reason to believe the matter would be settled satisfactorily.

In other Blue Shield actions, the House of Delegates authorized Blue Shield to negotiate with labor and management on new contracts which vary from standard Blue Shield programs and involve higher ceiling limits on income and payments to doctors. The action was the result of a resolution submitted by the Range Medical Society which includes the northern part of St. Louis County, also Itasca and Koochiching counties.

It became evident during the course of discussion that the plans approved would serve as a pilot plan in an area where negotiations with mining and steelworkers unions often require immediate action.

The sponsors of the resolution indicated that approval of such emergency negotiations would be of benefit to both medicine and labor. The House of Delegates, in giving its approval to the pilot plan, said that Blue Shield could negotiate with labor and management only if the final contract, in all of its terms, were approved by the local medical society and the Council of the Minnesota State Medical Association.

Dr. Clarence Jacobson, Association President, pointed out to delegates that the development would provide patients with a wider freedom of choice of doctors. According to Doctor Jacobson, a practicing physician in Chisholm, counties in the Iron Range country have had good relations with labor and they should be continued.

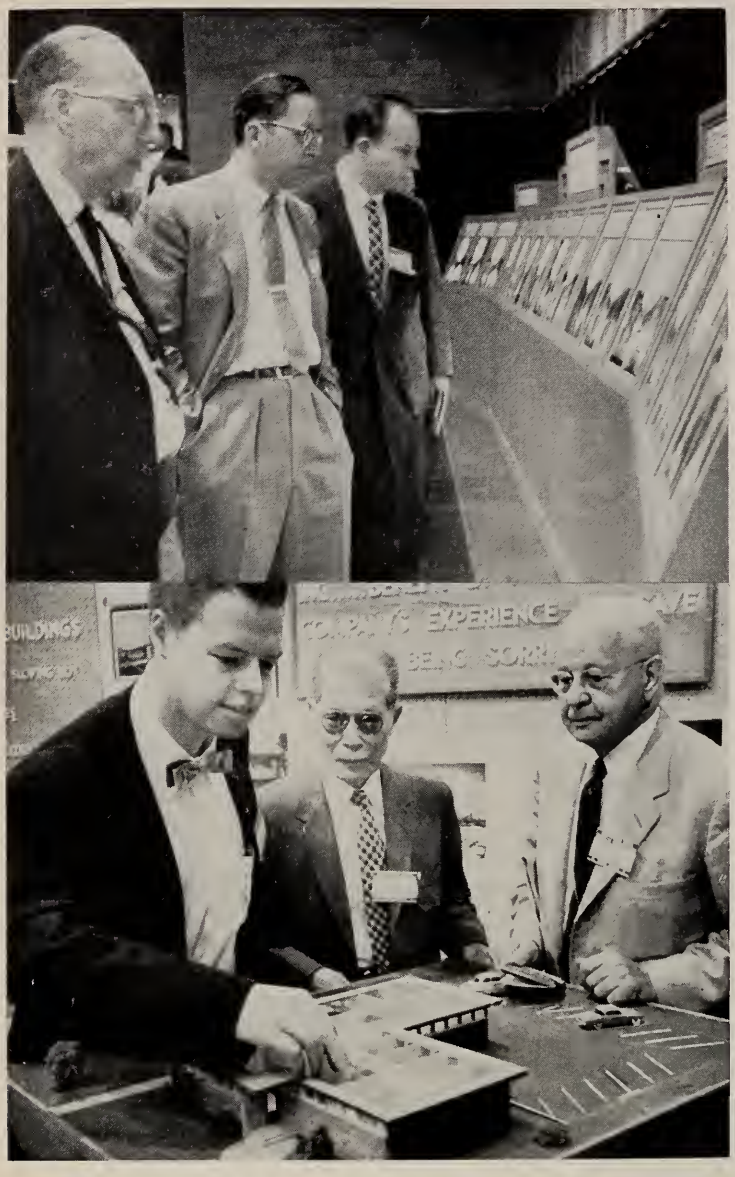
In addition to the Range resolution, the delegates considered the resolution introduced by the Ramsey County Medical Society. The resolution from the Ramsey County Medical Society was unanimously adopted by the House of Delegates as follows:

> WHEREAS, the physicians of Ramsey County most strongly insist that professional service rendered by physicians and the arrangements for payment for medical service must remain under the direction of doctors of medicine,
>
> THEREFORE, BE IT RESOLVED, that we most strongly insist that the Blue Cross not extend out-patient coverage in the form of diagnostic procedures to their subscribers.

The remaining resolutions were referred to the Council for further consideration.

Miscellaneous Resolutions Considered

Among resolutions in other fields which received unanimous sanction of the delegates was one from the Zumbro Valley Medical Society which proposed to recommend to the United States Postmaster General the printing of a commemorative stamp memorializing Drs. William J. and Charles H. Mayo.



Another called for a poll of members on the question of compulsory Social Security coverage for physicians. A new poll on the question was ordered by the delegates and will be conducted this year. This will be the third such poll conducted in the last five years by the Association.

Saint Paul Medical School Approved

Still another resolution called for approval of the Minnesota State Medical Association for a possible new medical school in Minnesota.

The resolution pointed out that:

1. The American Medical Association, the Association of American Medical Colleges, the Surgeon General's

SCIENTIFIC EXHIBITS FEATURED—Viewing a scientific exhibit *(above)* at the Auditorium sponsored by the Mayo Clinic and Mayo Foundation are, left to right, Drs. M. J. Lindahl of Sherburne, A. F. Johnson of Isle, and Alex Lowe of South St. Paul. A scale model of a hospital, *(below)* complete with parking lot and miniature cars, attracted the attention of three physicians attending the annual meeting of the Minnesota State Medical Association. Admiring the display, one of more than 100 set up in the Mayo Civic Auditorium Arena, are, left to right, Dr. Karl Helwig of Kerkhoven, Dr. Kano Ikeda of St. Paul and Dr. F. H. Magney of Duluth.

MEDICAL AUXILIARY OFFICERS — Mrs. M. F. Fellows of Duluth, left, retiring president of the Woman's Auxiliary to the Minnesota State Medical Association, was succeeded by Mrs. W. P. Gardner of St. Paul, second from right, in an election at the 38th annual meeting of the auxiliary at the Kahler Hotel. Second from left is Mrs. W. A. Merritt of Rochester who was elected president-elect of the state organization. Mrs. Martin VanHerik of Rochester, right, is the new president of the Zumbro Valley Medical Auxiliary.

Special Committee, and many other authoritative sources have pointed out the shortage of medical manpower that will develop in the United States during the next two decades.

2. The consensus of this authoritative opinion is that approximately twenty new medical schools must be established to diminish this shortage.

3. These twenty medical schools must be established in addition to the complete expansion of present medical school facilities and the City of St. Paul and the State of Minnesota have been adjudged as a favorable climate for medical education.

4. Sufficient clinical material has been demonstrated to be available in the Twin Cities to support an additional medical schools teaching program.

The Ramsey county sponsored resolution urged that the Minnesota State Medical Association go on record as approving the establishment of a new medical school in the state, and further be it resolved that the Minnesota State Medical Association cooperate with any well organized effort toward the establishment of a new medical school in Minnesota.

Annual Meeting Changes Aired

One of the major tasks of the 1960 session was the final consideration of a report prepared by a special committee created by the Council to study and evaluate annual meeting procedures. This committee was appointed as the result of comments voiced in the 1959 session and the report also considered the criticisms and suggestions made at that time. The project was previously referred by the Council to a special Reference Committee of the House which reported on Monday, May 23.

Dr. John L. Falls of Red Wing was Reference Committee Chairman and the following actions were taken on the basis of recommendations of his committee and discussions from the floor of the House.

1. That House of Delegates sessions should begin on Saturday instead of Sunday, which is the customary day, in order to give more time for reference committee deliberations.

2. That the annual President's Address should be given at the first session of the House, just preceding the report of the Chairman of the Council.

3. That all resolutions should be sent in to the Speaker thirty days before the delegates' sessions convene in order to give time for the delegates to bring them to the attention of their county medical societies: That the name of the individual or society concerned be given and that the Reference Committee to which the resolution is referred hold a preliminary meeting at which those who are in favor and those who are opposed can be heard; also that the State Association provide legal consultation on the resolutions so that committees will be aware of legal implications in all instances and that all reference committees hold executive sessions, after the open hearings for the purpose of preparing their reports for the House of Delegates; further, that only portions of the reports which require action be read from the rostrum and that the remainder of the reports be duplicated and distributed to the delegates; that all committee chairmen be required to be present at the reference committee meetings where their reports are discussed; also that all non-functioning committees be eliminated.

4. That the President of the State Association should preside and that Fifty Club members be called on by name and that they be asked to stand but not be required to walk to the speaker's table.

5. That prizes, scholarships and recognitions, except for the Distinguished Service Award, be announced in the House of Delegates instead of at the banquet.

6. That the Chairman of the Committee on Local Arrangements be a voting member of the Committee on Scientific Assembly and that meetings of the latter be arranged so that he can attend.

7. That time limits be enforced on speakers at the scientific sessions.

8. That it is not the province of the reference committee to decide the place of scientific sessions in the over-all picture but that suggestions should be sent to the Committee on Scientific Assembly (which is a continuing committee) and evaluated for possible future adoption.

9. That a permanent committee of the House of Delegates should be created and instructed to evaluate and re-evaluate the official structure of the Association, since time available to the reference committee was too short to deal adequately with the numerous problems involved. Appointment of the new committee would be made by the Speaker of the House and the Council and representation should sufficiently include enough to cover all areas of the State. It was pointed out that nominations for officers are now governed by the By-Laws and it was understood that the question of nominations should not be referred for evaluation to the new committee.

10. That Duluth be eliminated as a regular meeting place until such time as adequate facilities are available and with the hope that they will be made available soon.

A resolution calling for the meeting to be held in St. Paul and Minneapolis, only, was rejected by the delegates. The committee also recommended, and it was unanimously approved, that other resolutions with respect to official structure, including representation for some officials from rural areas, be referred to the new committee of the House for study.

Doctor Dale Heads Public Policy Committee

Dr. Les N. Dale of Red Lake Falls was named Chairman of the Committee on Public Policy for the next biennium by the Council and the choice was ratified by the House of Delegates. Doctor Dale will fit the duties of this post which he has held since 1956 to the demands of a busy medical practice.

New Student Loan Fund Established

A new permanent loan fund for medical students at the University of Minnesota was established by the House of Delegates. On recommendation of the Council, approximately $13,000 was appropriated by the delegates for this fund and it will be available at low interest rates for students who have exhausted all of the loan possibilities made available to them through other sources and who might otherwise be obliged to abandon their careers in medicine.

At the same time, final details were agreed upon for an emergency loan fund to be called the "Herman M. Johnson Emergency Student Loan Fund" which will be used for short-term loans to tide medical students over financial crises. It will be available in amounts up to $200 without interest for periods of ninety days. A total of $4,000 has been appropriated for this fund of which $3,100 is

AWARD WINNER—Dr. Bror S. Troedsson, Minneapolis, is shown at his booth which won an award as the best scientific exhibit at the Minnesota State Medical Association meeting. Dr. Troedsson was presented a medal at the annual banquet Tuesday night. The exhibit depicts oscillometric arterial circulatory norms.

DISTINGUISHED SERVICE AWARD WINNER—Dr. William H. Hengstler received the distinguished service award for contributions to the welfare of the Minnesota State Medical Association and medicine in general, as chairman of the medical advisory committee since 1940. Since he returned from World War I in 1919, Dr. Hengstler has practiced in St. Paul as a physician and neurologist. He is a member of the staffs of several St. Paul hospitals.

FIFTY-YEAR PHYSICIANS HONORED — Three of the physicians who were cited for fifty years of practice at the Minnesota State Medical Association dinner Tuesday night are *(left to right):* Dr. Martin Larson, 76, St. Paul; Dr. Herman Kesting, 77, St. Paul; and Dr. F. E. Ellison, 76, Monticello.

a transfer of the Herman M. Johnson Fund held by the Association for many years. It is to be used for an appropriate memorial to the late Doctor Herman M. Johnson of Dawson. Doctor Johnson was a University Medical School graduate, a former president of the Association and first chairman of its committee on Public Health Education. Members of Doctor Johnson's family joined with the doctors in hearty approval for use of the fund as an appropriate memorial to Doctor Johnson.

Impartial Medical Testimony Plan Approved

On recommendation of the Council, the delegates also approved a plan for selecting panels of impartial medical experts to be turned over to the district judges of the state for their use whenever they feel there is any question as to medical testimony offered in their courts, or in pre-trial hearings. This is, essentially, the plan for impartial medical testimony which received preliminary approval by the House of Delegates last year. The experts will be picked by balloting under supervision of the Committee on Medical Testimony.

Interprofessional Relations Code Approved

Approval was also voted with a minor alteration, on Council recommendations for a Code of Interprofessional Relations for use of doctors and lawyers of the state. The code must still receive the final approval by the Minnesota State Bar Association at its meeting in July.

Another pilot operation in work evaluation to be carried on at the Kenny Institute in Minneapolis was also approved. This plan will provide work evaluation reports for patients with pulmonary disabilities and will operate in much the same manner as the pioneer unit for heart patients.

Labor Relations Function Added

A new function was added to the Committee on Labor Relations, recently created subcommittee of the Committee on Medical Service, with approval of the House. The committee will serve as a meeting ground for representatives of employers, of unions and of the doctors, to arrive at policies and iron out differences in administration of employee medical care plans and fringe benefits. Preliminary meetings of these groups have shown the value of such a committee.

New Officers Elected

C. L. Oppegaard, M.D., who has served as Chairman of the Council for the past nine years, was elected President of the Minnesota State Medical Association at the closing session of the House of Delegates. Doctor Oppegaard is affiliated with Crookston's Northwestern Clinic.

Other officers elected include:

L. E. Hammar, M.D., Mankato, First Vice President; E. W. Johnson, Jr., M.D., Rochester, Second Vice President; B. J. McGroarty, M.D., St. Paul, Secretary; Karl W. Anderson, M.D., Minneapolis, Treasurer; Donald McCarthy, M.D., Minneapolis, Chairman of the Council; H. M. Carryer, M.D., Rochester, Speaker of the House of Delegates; J. L. Falls, M.D., Red Wing, Vice Speaker; Alvin M. Jensen, M.D., Brownton, Councilor, Fourth District; George A. Sather, M.D., Fosston, Councilor, Eighth District; J. M. Stickney, M.D., Rochester, Delegate to the American Medical Association; A. O. Swenson, M.D., Duluth, Delegate to the American Medical Association; R. H. Wilson, M.D., Winona, Alternate Delegate; and Clarence Jacobson, M.D., Chisholm, Alternate Delegate.

Nineteen Honored for Fifty Years of Service

Nineteen Minnesota physicians who have completed fifty years of medical practice in Minnesota received special citations and awards at the annual banquet on Tuesday, May 24. Guest speaker for the banquet was Dr. Laurence M. Gould, President of Carleton College in Northfield. "Education for a World of Change" was the title of his address.

Also presented at the banquet was the Southern Minnesota Medical Association Medal given annually to an individual physician for preparation of the most outstanding scientific exhibit at the Meeting. The recipient of this year's award was Dr. Bror S. Troedsson of the Veterans Administration Hospital in Minneapolis. Doctor Troedsson's exhibit depicted Oscillometric Arterial Circulatory Norms. In addition, the Distinguished Service Award for outstanding contribution to the work of the Minnesota State Medical Association during the past year was awarded to Dr. William H. Hengstler of St. Paul. Doctor Hengstler has served as chairman of the Medical Advisory Committee of the Minnesota State Medical Association since 1940.

Physicians who received the Fifty-year Service Citation in 1960 include the following: Frank T. Cavanor, M.D., Minneapolis; Andrew Christiansen, M.D., St. Paul; Wallace H. Cole, M.D., St. Paul; James A. Johnson, M.D., Minneapolis; Herman Kesting, M.D., St. Paul; Charles Koenigsberger, M.D., Mankato; Martin L. Larson, M.D., St. Paul; Henry Lysne, M.D., Minneapolis; Axel S. N. Noran, M.D., Minneapolis; Justus Ohage, M.D., St. Paul; Leon J. Petit, M.D., Minneapolis; Monte C. Piper, M.D., La Canada, California; Irving A. Preine, M.D., Osseo; Nels O. Sandven, M.D., Paynesville; Theodore Satersmoen, M.D., Pelican Rapids; Max Seham, M.D., Minneapolis; Jalmar H. Simons, M.D., Aspen, Colorado; Fred C. Westerman, M.D., Montgomery; and Otto W. Yoerg, M.D., Minneapolis.

Receive AMA Certificates

Four Minnesota county medical societies received certificates from the American Medical Association for achieving 100 per cent or more of their goal in the 1959 AMEF campaign. The county medical societies named to receive awards were Wabasha, West Central, Goodhue and McLeod. Presentations were made by the Council.

American Medical Association

Report on Actions of the House of Delegates

Health care for the aged, pharmaceutical issues, occupational health programs, relations with allied health groups and relations with the National Foundation were among the major subjects involved in policy actions by the House of Delegates at the American Medical Association's 109th Annual Meeting held June 13-17 in Miami Beach, Florida. Total registration was approximately 20,000 including nearly 9,000 physicians.

A résumé of actions taken by the American Medical Association House of Delegates is as follows:

Health Care for the Aged

After considering a variety of reports, resolutions and comments on the subject of health care for the aged, the House of Delegates adopted the following statement as official policy of the American Medical Association:

"Personal medical care is primarily the responsibility of the individual. When he is unable to provide this care for himself, the responsibility should properly pass to his family, the community, the county, the state, and only when all these fail, to the federal government, and then only in conjunction with the other levels of government, in the above order. The determination of medical need should be made by a physician and the determination of eligibility should be made at the local level with local administration and control. The principle of freedom of choice should be preserved. The use of tax funds under the above conditions to pay for such care, whether through the purchase of health insurance or by direct payment, provided local option is assured, is inherent in this concept and is not inconsistent with previous actions of the House of Delegates of the American Medical Association."

The House also urged the Board of Trustees "to initiate a non-partisan open assembly to which all interested representative groups are invited for the purpose of developing the specifics of a sound approach to the health service and facilities needed by the aged, and that thereafter the American Medical Association present its findings and positive principles to the people."

In connection with an educational program regarding the aged, the House declared that "the American Medical Association increase its educational program regarding employment of those over sixty-five, emphasizing voluntary, gradual and individualized retirement, thereby giving these individuals not only the right to work but the right to live in a free society with dignity and pride."

Earlier, at the opening session, Dr. Louis M. Orr, retiring AMA president, had asked the House to go on record favoring more jobs for the aged, voluntary retirement and a campaign against discrimination because of age, whether it be forty or sixty-five. The House also gave wholehearted approval to Doctor Askey's urging that state medical societies take an active part in state conferences and other planning activities preceding the January, 1961, White House Conference on Aging.

Pharmaceutical Issues

In the pharmaceutical area, the House took two actions—one regarding mail order drug houses and the other involving the development and marketing of pharmaceutical products.

The House agreed with representatives of the pharmacy profession that the unorthodox practice of mail order filling of prescription drugs is not in the best interest of the patient. The statement pointed out that in this process the direct personal relationship, which exists between the patient-physician-pharmacist at the community level and which is essential to the public health and the welfare of patients, is lost.

The House also directed the Board of Trustees to request the Council on Drugs and other appropriate Association councils and committees "to study the pharmaceutical field in its relationship to medicine and the public, to correlate available material, and after consultation with the several branches of clinical medicine, clinical research, and medical education and other interested groups or agencies, submit an objective appraisal to the House of Delegates in June, 1961." The statement pointed out that certain proposals have been made which, if carried out, might impair the future of pharmaceutical research and development, thus retarding the progress of scientific therapy. It also said that the services of the pharmaceutical industry are so vital to the public and to the medical profession that an objective study should be made.

Occupational Health Programs

The House approved a revised statement on the "Scope, Objectives and Functions of Occupational Health Programs," which was originally adopted in June, 1957. The new statement contains no fundamental alterations in AMA policy or ethical relationships, but it adds important new material on the following points:

1. Greater emphasis on the preventative and

health maintenance concepts of occupational health programs.

2. A more positive statement of organized medicine's obligation to provide leadership in improving occupational health services by part-time physicians in small industry.

3. Increased emphasis on rehabilitation of the occupationally ill and injured.

4. Inclusion of the proper use of immunization procedures for employes, as approved by the House in 1959.

5. A more adequate statement on the need for teamwork with lay industrial hygienists in tailoring each occupational health program to the particular employe group involved.

In approving the revised guides for occupational health programs, the House also accepted a suggestion that the AMA Council on Occupational Health undertake a project to study and encourage the employment of the physically handicapped.

Allied Health Groups

The House approved the final report of the Committee to Study the Relationships of Medicine with Allied Health Professions and Services and commended it as "a monumental work." The report covers the present situation, future implications and recommendations, including guiding principles and approaches to activate physician leadership. The House strongly recommended that AMA activity in this vitally important area be continued and it approved the appointment of a Board of Trustees committee to carry on the work.

To develop physician leadership in promoting cooperative efforts with Allied health professions and services, the report suggested the following AMA activities:

1. A general conference should be held with allied scientists in the basic medical sciences and related disciplines for discussion of matters of common concern related to the creation of permanent, cooperative activities.

2. Specific exploratory conferences should be held with members of segments of science allied to a given area of medical practice with the national medical organizations concerned.

3. General and specific conferences should be held with professional and technical assistants on education, recruitment and coordination of contributions.

4. Through meetings and publications, reciprocal exchange of information should be provided between physicians and allied scientists and members of health professions.

5. Effective, continuing liaison should be established between AMA representatives and professional and technical personnel.

National Foundation

The House took two actions involving relations between the medical profession and the National Foundation. It adopted a statement of policies for the guidance of state medical associations and recommended that they be adopted by all component medical societies. These policies cover such subjects as membership of medical advisory committees at the chapter level, the function of these committees, and basic principles concerning financial assistance for medical care, payment for physicians' services and physicians' responsibilities for constructive leadership in medical advisory activities.

In another action, the House directed the Board of Trustees to authorize further conferences with leaders in the National Foundation on the problem of poliomyelitis as it relates to the betterment of the public health and to consider further joint action toward the eradication of polio. The House commended the National Foundation for its outstanding service in the attack against polio, but pointed out that much work remains to be done in public education, vaccination, continuing assistance for polio victims and continued research.

Miscellaneous Actions

The House also:

Strongly reaffirmed its support of the *Blue Shield concept* in voluntary health insurance and approved specific recommendations concerning AMA-Blue Shield relationships;

Approved a contingent appointment of not more than six months for *foreign medical school graduates* who have been accepted for the September, 1960 qualification examination;

Agreed that the American Medical Association should sponsor a *second National Congress on prepaid health insurance;*

Approved a Board of Trustees request to the Postmaster General for a stamp commemorating the *Mayo Brothers;*

Decided that the establishment of a home for *aged and retired physicians* is not warranted at this time;

Approved the establishment of a new *"Scientific Achievement Award"* to be given to a non-physician on special occasions for outstanding work;

Approved the following schedule for future *annual meetings:* Atlantic City, 1963; San Francisco, 1964, and New York City, 1965;

Approved the objectives of the AMA *Commission on the Cost of Medical Care* established by the Board of Trustees and headed by Dr. Louis M. Orr, immediate past president of the Association;

Urged individual members of the Association to take a greater interest and more active part in *public affairs* on all levels;

Reaffirmed its opposition to compulsory inclusion of physicians under Title II of the *Social Security Act* and recommended immediate action by all AMA members who agree with that position;

Medical Education

MINNESOTA MEDICAL FOUNDATION

The Minnesota Medical Foundation, a non-profit organization of physicians, alumni and citizens supporting the University of Minnesota Medical School, has announced adoption of an expanded support program for the 1960-61 school year.

Its board of trustees is completing plans to raise $62,500 from members and private donors which would make possible:

—Up to forty scholarship awards of $500 each to deserving medical students.

—A distinguished service professorship to be awarded to a selected member of the medical school faculty.

—Expansion of the medical bulletin, official journal of the medical school, with revised format.

—Awarding of research stipends to medical students during vacations and periods of elective medical education.

—Establishment of a special basic research fund to support the work and ideas of young investigators at the medical school.

Dr. Herman E. Drill of Hopkins, president of the foundation, said enactment of the total program would depend on availability of funds, but that the 1,600 member organization had rededicated its present resources and energies to the long-term assistance of the University medical school at the University.

He named Alan W. Giles, Minneapolis life insurance executive, as chairman of the foundation's fund raising committee. Other committee heads are Dr. H. Mead Cavert, scholarships awards; Dr. Wesley W. Spink, editorial; Dr. E. B. Brown, Jr., membership; Dr. R. S. Ylvisaker, liaison; Dr. John A. Anderson, research awards; and Malcolm B. McDonald, finance.

"Our program," said Dr. Drill, "is designed to help the medical school maintain its high standards in the training of tomorrow's physicians. Only a portion of this increasingly costly process can be met by legislative appropriation. To fill the gap, the nation's eighty-five medical schools have already come to rely heavily on voluntary gifts from alumni, citizens, industry and foundations."

He said the Minnesota Medical Foundation's new program has emerged from recommendations of a 1958 faculty committee which surveyed the present and future needs of the University of Minnesota medical school. The committee was headed by Dr. Arnold Lazarow, head of the anatomy department and vice president of the foundation.

The foundation recently received a $2,000 grant from the Minnesota State Medical Association with which to launch and administer a special emergency loan fund for medical students.

AMA HOUSE OF DELEGATES

(Continued from Page 503)

Called for a review of existing and proposed legislation pertaining to *food and color additives,* with the objective of supporting appropriate measures which are in the public interest;

Urged reform of the *federal tax structure* so as to return to the states and their political subdivisions, their traditional revenue sources;

Asked state and county medical societies to make greater use of AMA *recruitment materials* in presenting medicine's story to high schools;

Requested the Board of Trustees to initiate a study of present policy regarding the required content and method of preparing *hospital records;*

Directed the Board of Trustees to develop *group annuity* and *group disability* insurance programs for Association members; and

Expressed grave concern over the indiscriminate use of *contact lenses.*

Election of Officers

Dr. Leonard W. Larson of Bismarck, North Dakota, former chairman of the AMA Board of Trustees and of the AMA Commission on Medical Care Plans, was named president-elect by unanimous vote. Doctor Larson will succeed Dr. E. Vincent Askey of Los Angeles as president at the Association's annual meeting in June, 1961.

The AMA 1960 Distinguished Service Award, one of medicine's highest honors, was given to Dr. Charles A. Doan, who will retire next year as dean of the Ohio State University College of Medicine and director of the Health Center in Columbus, Ohio. In addition to Dr. Leonard Larson, new president-elect, the following officers were named: Dr. William F. Costello of Dover, N. J., vice president; Dr. Norman A. Welch of Boston, re-elected speaker of the House; Dr. Milford O. Rouse, Dallas, Texas, re-elected vice speaker.

Dr. Gerald D. Dorman of New York City was elected to the Board of Trustees to succeed Doctor Larson, and Dr. James Z. Appel of Lancaster, Pa., was re-elected to the Board.

Elected to the Judicial Council, to succeed Dr. Louis A. Buie of Rochester, Minnesota, was Dr. James H. Berge of Seattle.

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

FRENCH DOCTORS "STRIKE" AGAINST GOVERNMENT MEDICINE

French physicians and dentists recently initiated a strike aimed at the government rather than the patients. According to one report, the government was seeking to limit the fees charged to Frenchmen eligible to receive state aid. According to the new schedule, physicians would receive $2.00 per office call in Paris. The current fee in Paris is $3.00 to $4.00. The fees are usually lower in the provinces.

The medical show of protest was in the form of a twenty-four-hour strike. During this time physicians in Versailles and other Paris suburbs refused to handle anything but emergencies.

In other sections of France, doctors launched a "paper strike" refusing to sign certificates required by patients in order to recover medical costs from the government. In many instances, physicians complicated government claim processing procedures by substituting personal stationery receipts.

Workmen's compensation claims were often marked "permanent incapacity possible," with the result that lengthy judicial inquiries were found necessary in many cases.

MEDICARE HEAD SAYS FEE RAISES ARE INFLATIONARY

Physicians should be satisfied with their Medicare fee schedules "for some time to come," according to Brigadier General Floyd L. Wergeland, Executive Director of Medicare. "We believe we are paying physicians' fees that probably approach the upper limits of fairness," the Medicare head told a recent meeting of the Dependents' Medical Care Advisory Committee. "It is not sound policy for us to accept inflation as a justification for increasing the fee schedules."

NECESSITY OF VOLUNTARY HEALTH CARE FOR THE AGED EMPHASIZED

Dr. F. J. L. Blasingame, Executive Vice President of the American Medical Association, in a recent address to the Annual Meeting of the Health Insurance Association of America in Dallas, Texas, said "it would be a tragic error to abandon voluntary health care financing for any segment of the population—young or old."

He said the "phenomenal progress" of voluntary health insurance paralleled advancements in medical care itself and that only this kind of competitive, private enterprise was capable of developing the best coverage for the American people.

"I am afraid that the starry-eyed benevolence purveyors who support Forand-type legislation are working under a delusion. They seem to think that good health for all the aged will arrive the moment a law of compulsion is passed."

"It was unbelievable," he added, "to watch these Pied Pipers operate and to see years of work and study on voluntary health insurance for the aged trampled under foot by self-styled experts."

Crash Program Necessary?

Arthur M. Browning, Chairman of the Health Insurance Council and Vice President in Charge of Group Insurance, New York Life Insurance Company, told the gathering of executives from 270 insurance companies that "a crash program to end all crash programs may prove to be the only way to defeat the forces of collectivism."

Mr. Browning said if some type of federal plan for medical care for the aged is enacted this year, it would hasten the nationalization of medicine and insurance. If no such legislation is enacted this year, he said, "the race between voluntary plans and some federal plan for the aged during the next two years will make the four-minute mile appear to be a leisurely stroll." He added:

"The job of covering the remaining aged which otherwise might proceed over a period of years, may have to be done almost instantaneously."

Substantial Progress Reported

Mr. Browning reported that the "substantial progress" already made toward solving problems among insurers, physicians, and hospitals "can be the basis for confidence in our ability to solve current and future problems."

Among areas of recent progress he listed: simplification of claim forms; development of more efficient methods for insured individuals to enter

hospitals without the necessity of cash down payments; development of "meaningful and reliable" data and statistics on health coverage; opening of wide, new channels of communication among the three professions; and common efforts toward stabilizing health care costs.

MEDICAL CARE PAYMENTS FOR NEEDY RISE SHARPLY

Medical payments for the indigent under four Federal-state programs have risen more than 100 per cent in a five-year period. This finding is based on a new health insurance institute study, with figures supplied by the Social Security Administration. In 1953, medical-care vendor payments for the aged, dependent children, the blind, and persons receiving disability payments totaled $106 million; in 1958, it came to $265 million. Total payments for all four programs in 1958—food, clothing and housing, as well as medical aid—were $2.9 billion, of which the Federal government contributed 60 per cent.

Another survey indicates that an annual total, well in excess of $400 million, is in prospect. In March, 1960, payments for that month were $24,769,124 for persons on old age assistance; $5,023,068 for dependent children; $680,278 for the blind, and $4,112,308 for the permanently and totally disabled. The aggregate, about $35 million, is at an annual rate of $420 million.

Tax Exemption Advice Given

Hospitals, nursing homes, foundations, and other institutions applying for tax exemption are requested by the Internal Revenue Service to list full and complete names and addresses of all donee organizations.

Processing of a great many applications are delayed because applicants fail to provide correct corporate or legal names of recipients of their benefactions.

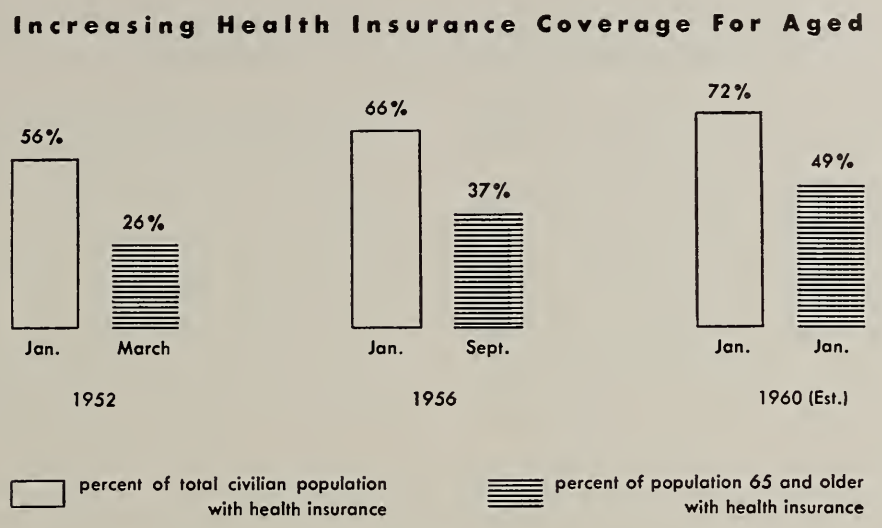
Bureau of Labor statistics show that "medical care" for the month of April rose 0.3 per cent over the March figure. By comparison, the Index was 155.5 or 55.5 per cent higher than the 1947-49 average.

The following statistics were revealed in the quarterly breakdown of medical care. The highest item—hospital rates—had an index of 220.6. Physicians' fees, considered apart from all other items, stood at 144.1, well above surgeons' fees, 128.8. For dentists' fees, the index was 136.8. Least expensive components of medical care, based on 1947-49 average=100, were prescriptions and over-counter drugs. Their composite index was 123.0.

NEW TAX RULING GIVEN ON MEDICAL COSTS FOR DEPENDENT PARENTS

The tax law has been changed by Congress so that a taxpayer may now deduct the full amount of any medical or dental expenses which he pays on behalf of his or his spouse's dependent parents, provided they are at least sixty-five years of age before the end of the taxable year. This marks a change from the previous law which allowed deductions not exceeding 3 per cent of the taxpayer's adjusted gross income.

WORTH WATCHING . . .



- Congress may attempt to tack an amendment to pensions for self-employed persons legislation placing doctors under the social security system.
- The New York Legislature recently killed a bill which would have licensed chiropractors in that state.
- Congress has been asked by U. S. Comptroller General Joseph Campbell to pass a law which would enable the government to recover millions of dollars which are currently spent each year for hospital and medical care in negligent third-party cases. Senator Harry F. Byrd, of Virginia, has stated that he will sponsor and press for the enactment of legislation which would correct this situation. Senator Byrd is Chairman of the Joint Committee on Reduction on Nonessential Federal Expenditures.

Many of the abuses have come from the military personnel. It has been pointed out that each year Uncle Sam spends in the neighborhood of $10.5 million to care for military personnel in hospitals and otherwise provide medical service as the result of private automobile accidents. Presently, the Department of Defense has no legal authority to recover losses from a negligent third party or from proceeds paid by a third party to the patient.

Presently, the Federal Employes' Compensation Act enables U. S. to recover certain costs of medical and hospital care rendered to civilian Federal workers. To a limited degree, the Veterans Administration has been getting some reimbursment in

comparable cases, but under a general provision of the law rather than specific authorization, which the Comptroller General and Senator Byrd are now recommending.

Association said, another 15 per cent, or 2.4 million persons, are officially classified as indigent, and provision is made for their medical needs through Old Age Assistance, supported by Federal-state

HALF OF AGED HAVE HEALTH COVERAGE

Forty-nine per cent of all Americans sixty-five years of age or older had health insurance protection against the costs of ill health at the beginning of 1960, according to the Health Insurance Association of America.

Of the 15.7 million persons in this age group, an estimated 7.7 million had health insurance, said the Association in issuing the first analysis made on a nationwide basis since early 1958 of the extent of health insurance coverage among "senior citizens." The report was based on coverage trends revealed in government and private surveys taken during the last decade and on developments in the health insurance business.

Because of accelerated activity by insuring organizations in this area, the growth of health insurance protection among persons sixty-five and older during the past eight years has been at a more rapid pace than for the population as a whole, according to the Association, which is composed of 270 insurance companies.

In early 1952, one out of every four senior citizens had health insurance, and now one out of two are so protected. Over the same period, the growth in coverage for the total population was from nearly six out of every ten persons to a little more than seven out of ten.

In addition to the 49 per cent of the sixty-five-and-over who now have health insurance, the matching fund programs. Such persons also receive money for food, housing, clothing, and other needs.

Government Surveys

According to the U. S. Department of Health, Education, and Welfare, 26 per cent of senior citizens had health insurance in March 1952, and by September 1956, this figure has grown to 37 per cent.

The most recent survey in this field was made in Spring 1958 by the National Opinion Research Center of the University of Chicago, which found that 43 per cent of senior citizens had health insurance. The rate of growth from 1952 to 1958 averaged out to a little less than 3 per cent a year, reported the Association.

The introduction of new insuring techniques has marked the increased activity in the sixty-five-and-over field by insuring organizations, according to Association spokesmen. One technique has been the mass-enrollment approach of issuing health insurance to large groups of aged persons in a state.

Many of the estimated fifty-one million persons now covered by group insurance policies issued by insurance companies will be able to continue their insurance after retirement, generally with part or all of the premium paid by the employer. Other workers will be able to convert their group insurance to individual policies.

Public Health

EXTENSION OF HOME NURSING CARE SERVICES TO THE ILL AND DISABLED IN RURAL MINNESOTA

In Minnesota, there were an estimated 335,000 persons over sixty-five on July 1, 1958. The following May 15 there were 14,583 licensed nursing home beds. With but four and one-third beds per thousand persons over sixty-five, many of whom suffer from a chronic disease or disability, it follows that most of those over sixty-five reside in private homes. Undoubtedly, when needed, home care is best and is the only practical solution when such large numbers are involved. Home nursing care, with other community services, can do much to improve the welfare of these oldsters.

To provide additional nursing service, several counties maintain rosters of registered nurses and licensed practical nurses who are willing to give home nursing care services in their communities on a fee basis. The public health nursing agency can refer the family to nurses who are available for home nursing care. There is no statistical information available on the use of this service or fees collected because, after the initial referral, the matter of services and fees therefore concerns only the patient, the nurse, and the physician in charge of the case, and no agency records are kept. Development and use of such rosters and referral system should be encouraged, especially in areas with low population density where travel would be excessive, were a single county nurse to provide this service.

Among the seventy-three counties in Minnesota with organized public health nursing services, fifty-three counties have only one public health nursing position, fourteen counties have two positions, one county has three positions, three counties have five to eight positions, and two counties have ten to fourteen positions. Most public health nurses serve from 15,000 to 30,000 people. A long established ratio is one public health nurse per 5,000 population. Without some plan to provide additional nursing staff, it appears unlikely that home nursing care services can be increased to any appreciable extent.

In 1955, the Legislature authorized county public health nursing services to employ licensed practical nurses and registered nurses to provide home care services on a fee basis. In 1959, as a result of a Legislative act, the Minnesota Department of Public Welfare instituted a homemaker service with a view to keeping the family intact and avoiding the cost for institutional care. While several counties have authorized a fee for home nursing service under the 1955 statutes, the Rural Hennepin County Nursing Service and Steele County are the only agencies operating such a service. In 1958, the Department conducted a pilot study in Steele County which involved the employment of a licensed practical nurse to assist the county public health nurse to better meet the home nursing care needs of residents in the county. This project showed the values in terms of money and service of such a plan.

In order to give impetus to the extension of home nursing care services it is proposed that funds be made available, within budget limitations, to provide eligible counties a grant-in-aid which they would use to employ a registered or licensed

NURSING SERVICE IN MINNESOTA
(Exclusive of Minneapolis, St. Paul and Duluth)

Year	Total Patient Visits	Total Therapeutic Nursing Visits	Per Cent of Therapeutic Visits to Total Visits	Total Adult Health Visits*	Total Adult Therapeutic Visits	Per Cent of Therapeutic Visits to Adults
1957	167,148	23,486	14.05	41,341	15,970	39
1958	156,982	22,003	14.01	42,600	15,631	37
1959	130,819	22,771	17.4	41,062	19,558	48

RURAL HENNEPIN COUNTY NURSING SERVICE

Year	Therapeutic Home Visits for Adult Health	Per Cent of Total Home Visits	Fees Received	Average Fee Received Per Visit
1958	4,231	40	$1,946.75	$.46
1959	5,192	43	2,970.90	.57

practical nurse to establish or extend home nursing care services—$1,500 would be granted for the first twelve months, $1,000 for the second twelve months, $500 for the third twelve months, and nothing thereafter. It is believed that assistance for three years should demonstrate sufficient values of such a service so that participating counties would be willing to carry on at their own expense, or that such grants might, to meet a demonstrated need, be continued with funds requested from and appropriated by the Legislature. Grants-in-aid would be contingent upon the county adopting a fee system on a sliding scale in accordance with the 1955 statutes (Section 145.123). It is estimated that $10,000 might be used the first year. Subsequent amounts would depend upon development of such services.

In Minnesota, exclusive of Minneapolis, St. Paul and Duluth in 1959, nursing visits for home care have increased as shown in the accompanying table.

FOOD SERVICE AND LODGING CONTROL

The State Board of Health has long been aware of deficiencies in its program of lodging and food service control. These deficiencies are inadequate staff, to make the necessary inspections and carry on educational work, and the present antiquated laws. For many years following the establishment of the program in a separate department in 1903 and following its transfer to the Health Department in 1925, the principal concern was in the area of lodging. In the past twenty or more years, greater emphasis has been placed on sanitation of food service. The justification for this emphasis lies in the fact that food is by far the leading source of intestinal illness. Although such illnesses are poorly reported, national figures show that food causes about thirty times as many outbreaks as water and twenty times as many as milk.

At the request of the Department, the Public Health Service in 1952 made a study of the existing program. The report pointed out several defects, most of which have been corrected, but the principal emphasis was on the need for increased personnel and clarified legislation. In order to secure the support of the food service and lodging industry, the Department outlined a proposed program of expansion, which would involve considerable increase in license fees, and presented it to the various associations representing the industry.

After agreement was reached, a bill was introduced in 1955 too late for consideration. In 1957, the bill became involved in a discussion of whether this program should not be in the Department of Agriculture. In 1959, considerable progress was made but objection was raised to the length of the bill and the size of fees. It is proposed to introduce another bill in 1961 with the specific sanitation requirements removed for adoption as regulations by the Board. Another objection was to the proposal for dedication of license fees to finance the program. The legislature opposes this principle on which the industry insists if the fees are to be raised from those that have been in effect since 1905.

In developing this proposed legislation, the Department has made every effort to eliminate duplication with other State departments and local agencies, and has endeavored to delegate inspections to qualified local health departments where possible.

Persons who advocate transfer of this activity to the Department of Agriculture allege that since that department regulates production, processing and manufacture of food products, it should also regulate the places where food is served. Of the several areas of food control, i.e., production, "food and drug" activity, wholesale and retail, and food service, the latter is the one in which the food is most susceptible to changes that affect health and the one in which educational endeavors are the most effective. The Health Department program makes an effort to develop an awareness of the need for hygienic food service rather than employing the enforcement measures that are effective in other areas.

Authority for food service control is vested solely in the health department in thirty-eight states and jointly in the health department and another agency in four others. In only six states is this program participated in by the department of agriculture. Nationally the Public Health Service is responsible for food service control on interstate carriers and for development of advisory codes for use by states and other governmental subdivisions. The Federal Food and Drug Administration is in the Department of Health, Education and Welfare. The Commission on Organization of the Executive Branch of the Government (Hoover Commission), in January 1949, went so far as to recommend transfer to the Food and Drug Administration and the Public Health Service many of the functions traditionally centered in the Federal Department of Agriculture because of their relation to public health.

Tumor Clinic

Every Four Years An Outstanding Opportunity To Come Up-To-Date On Cancer

This year . . . 1960 . . . Minnesota doctors can attend this international symposium in Minneapolis . . . when the University of Minnesota hosts the Fourth National Cancer Conference on its campus, September 13, 14 and 15.

Sponsored by the American Cancer Society and the National Cancer Institute, the Conference will bring clinicians, research workers and cancer specialists from around the world to the Twin Cities. Invitations have been sent to all physicians in the United States. Attendance is expected to approach 3,500.

Typical of the cancer specialists who will attend the meeting are:

ERIC BOYLAND, Ph.D., D.Sc.

London, England

Dr. Boyland is a professor of biochemistry at the University of London and was recipient of the Judd Award for Cancer Research in New York in 1948. He will participate in a special evening session on Wednesday, September 14, on "Cancer in the World Around Us." Dr. Boyland will present a paper on *Food Additives and Contaminants.*

NIKOLAI BLOKHIN, Ph.D.

Moscow, USSR

Dr. Blokhin heads the Institute of Experimental and Clinical Oncology of the USSR Academy of Medicine in Moscow. He will participate in a session on "Cancer of the Male Genitourinary Tract" on the second day of the conference.

SIDNEY FARBER, M.D.

Boston, Massachusetts

As a professor of pathology at Harvard Medical School's Children's Hospital, Dr. Farber is pathologist-in-chief and chairman of the Division of Laboratories and Research at Children's Medical Center. He is founder and scientific director of the Children's Cancer Research Foundation. With his interest in tumors and pathology in infancy and childhood, he received the annual National Divisional Award of the American Cancer Society for Massachusetts in 1958. He will chair a session on Leukemias and Lymphomas on Wednesday.

Southern Minnesota Medical Association

To Meet September 12

The annual meeting of the Southern Minnesota Medical Association, scheduled September 12 in Mankato, will provide Category I credit for members of the Minnesota Academy of General Practice.

During the morning and afternoon sessions of the meeting, a total of twenty papers of general interest to general practitioners will be presented. From noon until 2 p.m., the annual business meeting of the Association will be held during a complimentary luncheon.

Concluding the day-long meeting will be the evening program, featuring Dr. Ed Litin of the Mayo Clinic.

Papers to be given in the morning will be:

"A Five Year Review of Erythroblastosis Foetalis in a Small Community," by Dr. John T. Olive and Dr. Donald B. Swenson, Mankato.

"The Management of Sinusitis" by Dr. C. F. Lake, Mayo Clinic.

"Pediatric Eye Problems" by Dr. Malcolm A. McCannel, Minneapolis.

"Is There a Steroid of Choice in the Treatment of Rheumatoid Arthritis" by Dr. Emerson Ward, Mayo Clinic.

"Periodic Familial Paralysis" (case report) by Dr. John E. Verby of the Olmstead Medical Group, Rochester.

A paper on mononeuropathies by Dr. Donald Mulder, Mayo Clinic.

A case report involving the differential diagnosis between strokes and brain tumor by Dr. H. J. Svien, Mayo Clinic.

"The Neuro-Ophthalmological Evaluation of Patients with Stroke" by Dr. Robert W. Hollenhorst, Mayo Clinic.

A paper concerning surgical management of strokes by Dr. F. Henry Ellis, Jr., and Dr. P. E. Bernatz, Mayo Clinic.

A case report entitled "Hemiplegia in Early Pregnancy" by Dr. William S. Chalgren, Mankato.

During the afternoon session, the following papers will be presented:

"The Surgical Management of Chronic Bullous Emphysema" by Dr. W. Robert Schmidt, Minneapolis.

"Current Concepts of Treatment of Severe Bronchial Asthma" by Dr. William Sawyer Eisenstadt, Minneapolis.

"Some Complications of Myocardial Infarction" by Dr. Reuben Berman, Minneapolis.

"Congenital Upper Urinary Tract Lesions in Adults" (case report) by Dr. David P. Anderson, Austin.

"Urinary Infections in Adults" by Dr. Richard S. Rodgers and Dr. Bruce E. Linderholm, Minneapolis.

"Chronic Recurrent Urinary Tract Infections Children" by Dr. Arnold S. Anderson, Minneapolis.

"Recent Development in the Treatment of Obesity" by Dr. Lewis W. Younger, Winona.

"The Review of Orf" by Dr. John L. Farmer, Jr., Rochester.

"Surgical Treatment of Superficial Phlebitis of the Lower Extremity" by Dr. Thomas T. Myers, Rochester.

"Unusual Manifestations of Ophthalmopathy Associated with Graves' Disease" by Dr. D. A. Scholz, Dr. S. F. Haines and Dr. John W. Henderson, Rochester.

Minnesota Blue Shield

The phenomenal growth of Blue Shield medical care plans and their contribution to the economics and sociology of medical practice today may often be taken for granted by both the public and the medical profession, unless a simple restatement of accomplishments is made from time to time.

First, Blue Shield represents the most significant single development in medical economics ever voluntarily undertaken and successfully executed by the medical profession. More than that, the medical profession deserves much credit for having proven voluntary pre-payment plans are possible on a community-wide basis, and for paving the way for the commercial insurance industry to devise plans of their own in a field they had avoided previously.

In twenty years, the number of individuals covered by Blue Shield has grown from none to over 42 million. Throughout the United States during 1959, Blue Shield plans paid a total of $610,342,-407 in surgical-medical care expenses.

Included in this total is the $10,197,592.98 paid by Minnesota Blue Shield for surgical-medical care of its subscribers. This set a new annual record for Minnesota Blue Shield and brought the total paid since the Minnesota plan was organized in 1947 to nearly $61 million.

These impressive sums constitute a most important segment of the nation's medical economy and are evidence of the soundness and vitality of the Blue Shield idea which was undertaken with such a mixture of hope and doubt in 1939.

An important key to the success of Blue Shield has been its expansion of services covered, and the addition of new, bold programs such as Minnesota Blue Shield's Senior Citizens Plan, which met with such success in its May-June 1960, enrollment period.

Minnesota Blue Shield's recent addition of a diagnostic benefit likewise is in the tradition of broad coverage for as many services as possible throughout the community.

The constant search for new solutions to medical coverage problems has been the hallmark of Blue Shield during its first twenty years and promises a future of service to the doctor and the patient even more dramatic than its past.

That future, however, will not be without constant challenges from politicians and pressure groups, who will be quick to observe whether or not the Blue Shield plans and other voluntary pro-programs are "adequately" serving the country's needs. Blue Shield, at least, has proven it can serve those needs to the best interest of the public and the medical profession.

* * *

In one of the most significant actions affecting Minnesota Blue Shield taken by the Minnesota State Medical association at its annual convention in Rochester in May, the association authorized Blue Shield to negotiate with labor and management in developing contracts for employees.

This unprecedented action was taken by the House of Delegates of the State Medical Association following a request made by the Range Medical Society, which includes the northern part of St. Louis, Itasca and Koochiching counties, areas with a high concentration of miners and steelworkers.

The Range Society noted that these areas are frequently confronted with requests for negotiations with labor which require immediate action in medical care plans.

Such contracts would vary from standard Blue Shield programs in that they would involve higher ceiling limits on income and payments to doctors.

Authority was requested, therefore, to enter these emergency negotiations with labor and management to devise workable contracts for a given area.

Following successful results in the Range Medical Society's area, the authority may be extended to other parts of the state, it was said.

In granting the authority, the House of Delegates stipulated that Blue Shield could negotiate with labor and management only if the final contract, in all its terms, was approved by the local medical society and the Council of the State Medical Association.

Dr. Clarence Jacobsen, Chisholm, president of the Minnesota State Medical Association, said the development would provide patients with a wider freedom of choice of doctors.

The move was also approved by Dr. Robert P. Buckley, Duluth, councilor for the Ninth District.

THIRTY-FIVE DEATH WARRANTS FOR AN ASSOCIATION

The life of an Association is dependent upon its individual members. The number of associations, professional societies, and community service organizations which seek to also include the names of physicians on their membership rosters are almost innumerable. Certain responsibilities as well as privileges accompany the possession of a membership card for most associations.

Before joining an organization, the prospective member would do well to evaluate the future demands upon time, talent, and the extent of financial participation. To be active in a given organization or association will not infrequently require appointment to a committee which could require varying demands of time out of a daily work schedule.

Then, too, the possibility of becoming elected to an office with its accompanying responsibilities and duties must not be overlooked.

Failure to assume the obligations expected of an organization by its members may result in poor personal and public relations—internally and externally. Numerous are the laments of association or society officers who find that they have an impressively large roster with a "let Joe do it" philosophy.

Thirty-five rules to kill an association have been compiled by Vern Scofield of the Nebraska Press Association. To follow the rules cited by Mr. Scofield would, without doubt, produce the desired result.

Do you want to see your society or association live? The prescription is simple. *Don't* follow the following rules!

1. When you attend a meeting, vote to do something, then go home and do the opposite.
2. Don't come to the meeting.
3. But if you do come, come late.
4. If the weather doesn't suit you, don't think of coming.
5. If you do attend a meeting, find fault with the work of the officers and other members.
6. Never accept an office or committee appointment as it is easier to criticize than to do things.
7. Nevertheless, get sore if you are not appointed on some committee; but if you are, do not attend committee meetings.
8. If asked by the chairman to give your opinion regarding some important matter, tell him you have nothing to say. After the meeting tell everyone how things ought to be done.
9. Do nothing more than is absolutely necessary; but when other members roll up their sleeves and willingly and unselfishly use their ability to help matters along, howl that the Association is run by a clique.
10. Don't bother about helping get new members.
11. When a banquet is given, tell everybody money is being wasted on blowouts which make a big noise and accomplish nothing.
12. When no banquets are given, say the Association is dead and needs a can tied to it.
13. Don't ask for a banquet ticket until all are sold.
14. Then swear that you were cheated out of yours.
15. If you do get a ticket, don't pay for it.
16. If you are asked to sit at the speakers table, modestly refuse.

17. If you are not asked, resign from the Association.

18. Hold back your dues as long as possible, or don't pay at all.

19. If you don't receive a bill for your dues, don't pay.

20. When you do receive a bill for your dues postpone paying until the secretary writes for the money—then get sore because you were dunned.

21. If you receive a bill you've paid, resign from the Association or at least suggest to some of the members that Central Office tried to work you or is manipulating the accounts.

22. Don't tell the Association how it can help you, but if it doesn't help you, resign.

23. If you receive service without joining don't think of joining.

24. If the Association doesn't correct abuses in your neighbors business, howl that nothing is done.

25. If it calls attention to abuses in your own, resign from the Association.

26. Always think about and don't fail to talk about the "mote" in the other fellow's eye—never consider the "beam" in yours.

27. Keep your eyes open for something wrong and when you find it, resign, or at least raise plenty of dickens.

28. At every opportunity, threaten to resign and then get your friends to resign.

29. Agree to everything said at the meeting and disagree with it outside.

30. Always delay replying to communications from the Association, or better, don't answer at all.

31. When asked for information, don't give it, then

32. Criticize the Association for incompleteness of its information.

33. Get all the assistance the Association gives, but don't give it any.

34. Talk cooperation for the other fellow with you but never cooperate with him.

35. When everything else fails, blame the Secretary.

LEAFLET OUTLINES HEALTH INSURANCE USES, ABUSES

"Let's Use, Not Abuse, Health Insurance" is a new American Medical Association leaflet, based upon an AMA House of Delegates policy statement. It outlines the problem of health insurance abuse simply and strongly. It spells out some specific responsibilities that patients, hospital people, unions, employers, and doctors themselves share if we are to "hold the line" on these costs.

Here are some points emphasized in it:

- ★ Consider your health insurance an "investment." Know what it is, what it can and cannot do and how to use it properly.
- ★ Don't expect health insurance to pay every expense related to health maintenance.
- ★ Don't pressure your physician into hospitalizing you unnecessarily. Some procedures can be performed with equal safety and efficiency and greater economy in the physician's office.
- ★ Remember—you don't have to "collect" on your insurance to win. You win when you are spared the economic and related consequences of accident or illness against which your insurance protects you.

Though the American Medical Association has distributed copies of this new piece to key labor, hospital, insurance, farm and management groups as well as to the press, your help in circulating it to people in your area is needed. You may wish to obtain quantities for your own patients. Order copies from your state office.

History of Medicine in Minnesota

MEDICINE AND ITS PRACTITIONERS IN MOWER COUNTY PRIOR TO 1900

NORA H. GUTHREY
Stewartville, Minnesota

A well-known historian once said, in effect, that historians have learned that the most they can hope for is to establish facts beyond a reasonable doubt—that their raw materials are statements, and that statements must not be mistaken for facts. As the immortal Captain Bunsby remarked about a quite different matter, "The bearings of this observation lays in the application on it."

Now that more than a century of medical practice in Minnesota has elapsed, one who compiles a story of the practice and the practitioners of medicine in a county of the state prior to 1900 must consider himself not an author or a historian, but rather an editor, in the sense of selecting historical material.

This paragraph will serve in lieu of a detailed bibliography of the present notes on physicians of Mower County and their work. The writer has drawn much information from general histories of the county and the state, and for the purpose of verifying intercounty practice of medicine and the frequent changes in residence of the physicians, has referred to histories of medicine in other counties that have been published in MINNESOTA MEDICINE, beginning in 1938. In addition, numerous other sources have been helpful, among them official records and registers of various types relating to physicians; old issues of official medical journals since their beginning in the state; the *Transactions* of the Minnesota State Medical Society ("Association" from 1903); and old newspapers. Whenever possible, interviews with or communications from members of the families of the early physicians have been obtained.

About many of the numerous physicians who were in Mower County only a few months, a year, or perhaps a few years, there unfortunately has been little more available than note of name, place of practice, and probable duration of stay. There were, of course, various practitioners who were frankly itinerant, and there were quacks. The physicians who were best known are mentioned briefly in the

---

Mrs. Guthrey is a retired member of the nonmedical staff of the Mayo Clinic; a former member of the Publications Department; secretary and assistant to the late Dr. William J. Mayo, 1919 to 1939, inclusive; later, on special assignment in editing and compiling, and in research and writing on regional medical history (Houston, Fillmore and Olmsted Counties).

Acknowledgments.—Great credit is due to Dr. Paul C. Leck, Austin, Minnesota, who some years ago, as historian of the Mower County Medical Society, began collecting data toward the early medical history of the county. Many excerpts from his material are incorporated, without special designation, in this article.

Dr. O. H. Hegge of Austin has been materially helpful in discussing the practice of medicine in the county in the later eighteen nineties, and particularly in commenting on the organization of St. Olaf Hospital and the formation of the Mower County Medical Society.

Dr. Robert Rosenthal, of St. Paul, Chairman of the Historical Committee of the Minnesota State Medical Association, generously has supplied official data relating to many of the early physicians of Mower County.

Thanks are expressed to those members of the families of early physicians who co-operated in the effort to prepare accurate biographical sketches.

text; notes about them and all others believed to have been of the regular school or of other schools of practice recognized in their day are included in the series of biographical sketches or comments that follows the narrative.

Chiefly General History

Something of the early history of the county is presented to give a conception of the scene in which the pioneer physicians followed their profession. Those who are interested in greater detail are referred to the general histories of Mower County of 1884 and 1911, both of which provide fascinating reading and a wealth of information about pioneer settlers, early events, and development.

One of the nine southernmost counties of the state, Mower County is the third west from the Mississippi River. It is bounded on the north by Olmsted and Dodge Counties, on the east by Fillmore County, on the south by Iowa (Mitchell and Howard Counties) and on the west by Freeborn County. When, by degrees, the original vast counties of Minnesota Territory were divided into smaller counties, the present limits of Mower County were defined, in February, 1855; and on March 1, 1856, the county was organized and named in honor of John E. Mower, an early settler. The twenty townships were created, in four tiers of five townships each. On a map they appear, reading from west to east, and from the northern tier to the southern: Udolpho, Waltham, Sargent, Pleasant Valley, Racine; Lansing, Red Rock, Dexter, Grand Meadow, Frankford; Austin, Windom, Marshall, Clayton, Bennington; Lyle, Nevada, Adams, Lodi, Le Roy. They were divided early into sections. In April, 1858, they were empowered to maintain local governments. As population increased, towns were founded: The city of Austin came into being early in 1856; on April 17 two plats of Austin were recorded by two groups of citizens, but the actual site described in both was the same. Frankford, Hamilton (on the line between Mower and Fillmore Counties), Le Roy and Brownsdale soon followed. The other villages were established between 1857 and 1871. Nevada, Troy City, Two Rivers and others were laid out early but were not settled.

The land is gently undulating prairie, well watered by three main rivers, the Cedar, the Iowa, and the Root, and by their numerous tributary creeks; drainage is to the south, southeast, and northeast. There are few lakes, none of any great size, and there is very little marshy land. In the main, the soil is a rich sandy loam, suitable for cultivation. In the early years there were sufficient trees along the watercourses to supply the pioneers with fuel, but not enough to furnish lumber in abundance for building. There was much good building stone, however, in different parts of the county. A topographical feature which was to have civic and political importance is a strip of prairie running north and south in the central portion, dividing the county into the east side and the west side. The eastern, western, and southern parts of the county in general were settled first and most thickly.

Because of its situation inland, the future Mower County probably was not visited by any of the early explorers who traveled the main waterways of the territory which was to become Minnesota. The earliest recorded visit of white men was in 1835, when a military expedition from Fort Des Moines passed through the region. In 1836, Major Lawrence Taliaferro with a hunting party of officers from Fort Snelling reached this part of the county and camped overnight by the Cedar River, somewhere near where Austin now stands. With the group was Dr. John Emerson, the surgeon at Fort Snelling, and therefore it may be said that the first physician (excluding the Indian medicine men) to enter Mower County was a military surgeon on a hunting trip, sixteen years before the first white settler arrived and nineteen years before the first physician settled here. No doubt the trip was successful, for wild game abounded, then, and twenty years later. In the winter of 1840-1841, it

is said, a party of 150 Indians and their families was induced by Henry Hastings Sibley (then agent for the American Fur Company at Mendota and later the first governor of Minnesota) to conduct a great hunt in this region. The Indians' headquarters were a large stockade, the first structure built here by white men, located beside the Cedar River, north of the site of Austin. The fur company furnished the Indians with guns and ammunition at a price. By spring, the Indians had "killed 2,000 deer, fifty elk, as many bear, five panthers and a few buffalo." The pelts were bought by the fur company at a nominal cost. Until the land was opened to white settlement by treaties with the Indians signed in 1851, south central Minnesota was undisputed hunting ground of the Indians.

Once the territory was thrown open, immigration began, slowly for a few years, increasing tremendously between 1856 and 1860, and continuing into the seventies. As in other counties, the pioneers came from many different states and from different countries of Europe. They arrived on foot, on horseback—families with oxen and covered wagons—a few with horse-drawn vehicles. They crossed the Mississippi River at Dubuque and came up from Iowa, they came down from the settlements of St. Anthony and St. Paul, they crossed the Mississippi River from La Crosse to Brownsville, Houston County, where the first regional land office was, later came by way of Chatfield where a second land office was established, and made their way as best they could to find land and new homes. Most of them were farmers, sturdy, hard-working folk. Soon there came craftsmen, artisans, newspapermen, lawyers, and doctors. They followed the pattern long established, from east to west in the United States, of building homes—crude at first, breaking roads, opening farms, establishing schools and churches, founding villages, developing businesses and professional practices. Unlike the counties bordering the Mississippi River, Mower County attracted few if any of the stragglers from river traffic, nor did the region interest lumbermen, bonanza farmers, or to any great extent, the large numbers of medical quacks who imposed upon the counties to the east.

In the autumn of 1852, claims were staked by some hunters and trappers from Iowa who soon left and did not return. The first permanent settlers were probably the fourteen persons of the "McQuillan group," of three related families who settled near Racine. They arrived on July 4, 1852, after a trek of about three months from Ohio, via Dubuque, with ox teams and wagons. Toward the close of 1853 many settlements were made along the Cedar River, Deer Creek, and the Iowa River, but by the end of the year there were fewer than twenty families in the county, and less than 100 bushels of grain had been raised. The pioneers, except the few who had money enough to purchase supplies in Iowa, depended chiefly for food on wild game. Austin Nichols, after whom the city of Austin was named, hunted along the Cedar River in 1852, and drove his first claim stake in 1854. A. B. Vaughan was near the site of Lansing that year, and there was a Norwegian farmer near the site of Brownsdale. Entries of land claims in the western part of the county were filed in September, 1855. In Pleasant Valley Township (northeastern Mower County) John S. Peirson and his brother Frederick M. Peirson filed on claims in the summer or autumn of 1854; according to one history, these were the first claims filed in Mower County.

Mower County had its political flurries. On May 22, 1857, "through the machinations of J. M. Berry, member of the Legislature, sections 1 to 6, inclusive, in town 104, of ranges 14 and 15, were cut off from Mower County and annexed to Olmsted County." This long narrow piece of land was the much disputed "Mile Strip." With its annexation to Olmsted County, many early settlers became residents of High Forest Township. With the organization of the county, and of towns, came the celebrated contest between Austin and Frankford for the honor of being the

county seat. It was then that the West Side and the East Side became official, each with its political ticket: the People's Ticket (West Side) and the Union Ticket (East Side). The story of the Tin Box Courthouse, the little box that contained the essential records—its shunting between Austin, Frankford, and High Forest through the efforts of the political spirits most nearly concerned, has been told well and often and appears in many accounts. It is of some interest here that in the first general election in the county, on October 14, 1856, Dr. Orlenzer Allen, the second physician in the county and the first in Austin (April, 1856), was the successful candidate for the office of coroner; the East Side had nominated a layman. Finally, on June 1, 1857, by vote of the people, Austin became the county seat.

The depression of 1857, largely due to overpromotion of the proposed railway lines and inflation of real estate values, caused severe hardship temporarily and delay in development of the county, but in due time stability returned, and with actual operation of the railroads after the Civil War steady progress began. In 1859 the population of the county was 3,700, of whom 400 were Norwegians, 200 Irish, and fifty German. By 1874, Scandinavians made up about one-fourth of the population.

Mower County early had newspapers, well listed in the general histories of the county. In those first decades and until the early eighteen eighties, when the practice fell into disuse, it was the custom for physicians, many of them at least, to publish not only statements of office address and hours, but also to give, sometimes in great detail, their professional qualifications, and accounts of work done and results obtained.

A Partial Roster of Practitioners of Medicine in Mower County (1855-1899)

Probably the first physician to practice in Mower County was a Thomsonian practitioner, J. C. Jones, who came to Le Roy Township in 1855. His wife also practiced medicine. After a few years they moved on to Missouri to engage in farming. In 1855 also, E. J. Kingsbury was in Bennington Township, but whether he then practiced medicine has not appeared. In 1860 he went to Spring Valley, Fillmore County, where he practiced for ten years; in 1870 he returned to Mower County and in Le Roy practiced for many years. In April, 1856, Orlenzer Allen came to Austin, the first physician in the city, to be followed in September of that year by John N. Wheat, who spent the remainder of his long life there. Hiram L. Coon came in 1856 to Austin, for five or six years. John L. Martin, preacher, physician and farmer, known in various counties of southern Minnesota, was in or near Frankford from 1856 to 1874. Joseph Alloys, physician, Catholic priest, and farmer, settled in Lansing in 1857, and probably in the same year Erastus Belden and his son, Wallace P. Belden came to Frankford from Hamilton, where they had arrived in 1853.

In the next few paragraphs is given, by decades of arrival and place or places of practice, a partial list of others of the approximately 146 physicians who came to Mower County before 1900. Some remained a lifetime, many left soon for other counties of the state or for other states.

1860-1869.—Sixteen physicians came to Mower County between 1860 and 1869. W. C. Jones settled in Austin in 1862 for some seventeen years. F. Brewer and a Dr. Huffman came to the city in 1863. Dr. Bingham came to Le Roy in 1865 and remained two years. Rensselaer Soule began practice in Lansing in 1865; he moved to Austin in 1875, and died there in 1880. The only arrival noted in 1866 was a Dr. Lafayette, who practiced in Lansing three years. In 1867 three physicians arrived who became outstanding members of the medical profession of the county: G. M. Allsdurff had an extensive practice at Le Roy for many years; O. W. Gibson was

a valued physician and surgeon of Austin until his death in 1896; W. L. Hollister, who arrived in Lansing in 1868, and settled in Austin in 1871, had a long and useful career which ended with his death in 1921. In 1868 J. W. Corbitt settled in Le Roy, where he practiced until his death in 1881. In the winter of 1869-1870, S. P. Thornhill and his son F. W. Thornhill came to Austin, where the senior physician died in 1879, after ten years of devoted service to the sick. In 1872 F. W. Thornhill removed to Spring Valley. Albert Plummer, a physician of merit, was in Hamilton from 1869 to 1893, and in Racine from 1893 to 1911. E. S. Gibbs perhaps was in Austin in 1869. P. C. Berry came to Austin in 1869. J. A. Allen settled in Austin probably in the late sixties. In 1869 he became a member of the Minnesota State Medical Society, the first member from Mower County.

1870-1879.—The eighteen seventies brought some thirty-seven medical newcomers of various types to Mower County. Most of them stayed from a few months to a year or two. Of the total number Austin received twelve, Brownsdale ten, Lyle and Grand Meadow four each, Dexter three, Rose Creek two, and Adams, Lansing and Taopi one each. A. Truane, the first to practice in Lyle, came in 1870, and was followed the same year by a Dr. Tanner. Neither stayed long. J. W. Eighmy was in Brownsdale for a few years beginning in 1871. The next year S. W. Jenks came to Grand Meadow, J. P. Squires to Austin, and O. Wheelock to Rose Creek; all became well known. R. W. Simmons, the first physician in Dexter, arrived in 1872 and stayed two or three years. Three practitioners came in 1874, one each to Brownsdale, Le Roy and Austin, but none remained more than a year or two. Three more, in the same category, came in 1875, and five more in 1876. Among the seven who arrived in 1877 were G. W. Gray (first in Grand Meadow) who stayed until 1883, later going to Brownsdale; and Lyman D. Jackson, in Dexter two years and in Grand Meadow from 1879 until his death, in 1892. Four came in 1878, two to Austin, two to Brownsdale, none of whom left lasting records; and 1879 brought three, none of whom stayed long.

1880-1889.—The eighties brought twenty-nine new practitioners to Mower County —to Austin, Brownsdale, Le Roy, Lyle, Taopi—in about the proportions of the distribution in the previous decade, and one to Frankford. Of this group, fourteen are named here. C. S. Beaulieu, well known in different counties in southern Minnesota, came to Brownsdale in 1880 for about ten years. W. M. Dodd, an able young physician, spent a period in 1880-1883 in that village. Emma Backus Fairbanks, a resident of Austin since 1861, qualified as a physician in 1881; she died in 1887. S. P. Meredith came to Austin in 1882 for a few years, left, and in 1902 returned for a few months. Thomas Phillips practiced in Austin from 1882 to 1886. In 1883 F. M. Johnson opened an office in Brownsdale; in 1885 he went to Grand Meadow, for five years. Alexander MacDonald practiced in Austin from 1883 to 1897. Of importance in Austin was W. H. McKenna, who came from successful practice in Caledonia (Houston County) and served the community well until his death in 1932. C. H. Johnson, in Austin, and H. L. Knight, in Le Roy and Adams, became outstanding physicians of the county beginning in 1884. A. W. Allen, a son of the pioneer physician Orlenzer Allen, began in Austin in 1885 a professional career that ended with his death in 1940; for a few years after 1887 his brother A. O. Allen was in practice with him. W. A. Frazer in 1885 began a long term of practice in Lyle. Sarah Catherine Wilcox practiced in Austin in 1866-1891. Annette Corneveaux (Finn) was in practice in Austin from 1887 until her death in 1896.

1890-1899.—The last decade of the Nineteenth Century added perhaps forty-six practitioners of medicine to the roster of Mower County. As in previous decades,

some were scarcely more than visitors, others spent many years here as useful citizens and well-loved physicians. Of the forty-six, Austin attracted twenty, Lyle five, Dexter four, Adams, Grand Meadow and Le Roy three each, Rose Creek two, and Brownsdale, Waltham and Madison one each. Concerning three of the possible practitioners, the record is obscure.

Emma Washburn (Rodgers) was in Austin from 1891 to about 1909. F. E. Daigneau was a successful physician in Austin from 1892 until 1937, the year of his death. G. W. Dahlquist spent the period 1893-1898 in Adams. Fanny G. Kimball Fiester had an active career in Austin from 1893 until her sudden death in 1938. D. F. O'Connor spent about six years in Grand Meadow from 1893 to probably 1899. In December, 1893, O. H. Hegge and his brother C. A. Hegge began in Austin their initial practice, soon widespread, in a partnership that continued about thirty-seven years; Dr. O. H. Hegge, the surviving brother, in 1960, is in his sixty-eighth continuous year of practice. W. F. Cobb, a general practitioner of the best type, lived in Lyle from 1895 to his death in 1932, but had been known and respected in Mower County since 1874, when he settled in near-by Mona, Iowa. J. J. Finn spent 1895 and 1896 in Austin. M. J. Hart and A. E. Henslin were two outstanding and staunch physicians who settled in Le Roy in 1895. Dr. Hart moved to California in 1921; Dr. Henslin remained in Le Roy until shortly before his death in 1950.

In Austin in the middle and late nineties were William Coburn, a Dr. Hanson, perhaps, and W. V. Hanscom. For a time Dr. Hanscom was in partnership with Dr. Coburn. In 1898 H. F. Peirson began his practice of forty-two years in Austin, and G. J. Schottler, fifty years of service in Dexter. J. S. Beagle came to Rose Creek in 1897 and stayed until 1909. In 1898, M. G. Millet joined M. J. Hart in Le Roy for two years. W. W. Freeman came to Grand Meadow from Caledonia in 1898 and remained until 1904. Emma Adeline Keeney, for a year or so in partnership with Dr. Fiester, was in Austin from about 1898 to 1899. W. N. Kendrick came from Spring Valley in 1898 to join C. H. Johnson in Austin, and in 1905 returned to Spring Valley. C. H. Robbins, long well-known in Fillmore County, came to Austin in 1898; his death occurred in 1900. O. C. Maercklin was in Adams in 1899, perhaps earlier.

Conditions of Practice

The physicians who came to Mower County between 1855 and 1900 must have represented a typical cross section of the medical men of their day and also of the pioneers who settled the West.

One of the most welcome additions to the population of a new country was the physician. Whatever his educational qualifications, his labors were important. He did the best he could in the conditions under which he worked. In the earliest years the physician had a limited armamentarium. He carried—in saddle bags, in buckboard, whatever his transportation in those days of no roads or poor trails—a few drugs; perhaps calomel, aloes, Dover's powder, opium, spirits of niter, Spanish fly, Peruvian bark, and whiskey; a little tin box of smallpox scabs to use in vaccination; lancets for bleed-letting, and knife and saw for amputations.

As stated, many of the physicians who came to Mower County left after a few weeks, months or years, for other counties or other states; in the early eighties many went on to Dakota Territory. Those who stayed became important figures in the growing settlements and the rural communities. In the fifties and sixties (during the panic of 1857 and the period of slow recovery after the Civil War) physicians in general must have had a trying time economically, for notices similar to the following appeared frequently in the newspapers: "Wanted: Will our customers

bring some wood, corn and oats. Dr. W. C. Jones." (*Mower County Transcript*, November 11, 1863.) Some physicians farmed as well as practiced medicine, some opened drugstores on the side or in connection with their practice. It was before the day of the great pharmaceutical companies, and many, if not most, practitioners compounded their own medicines. It may be said here that the early physicians were not only druggists but also, on occasion, oculists and opticians, and dentists. There were travelling "eye doctors" and also traveling dentists for some time before stable practitioners of the specialties became permanent residents.

An old history of the county lists the early physicians as being of the "old school," which in general meant, or came to mean, allopaths or members of the regular profession. There were representatives of the eclectic school, the homeopathic, the physiomedical, and others, and a few of the "magnetic" persuasion. Some had the best training available in their day. In previous articles on regional medicine in Minnesota, the medical education available in the first half or three fourths of the century has been described in detail, and the names given of many of the best of the medical schools in the East and in the Middle West in those years. The usual procedure was to study with a preceptor until the student had enough confidence to strike out in practice for himself; or to obtain instruction from a preceptor preliminary to the brief college or university courses in medicine then offered. There soon came into existence many worthless, so-called medical institutions that gave certificates of graduation, the "diploma mills," the "sheepskin factories," which equipped with "credentials" numberless practitioners who imposed on the population. As a logical result there came the itinerant practitioners, of some professional qualification, perhaps, and the errant quacks; in one county of Minnesota there was a mule driver who used the letters "M.D." after his name, for such profit and prestige as they might give.

In that early period came the medicine shows, which attracted a portion of the public who were more or less credulous. Others of the population were impressed by the pseudoscientific vocabulary used by some of the traveling gentry, and by the advertisements of patent medicines, almost astronomical in actual numbers and in the number of cures claimed for them of every ill known to mankind. In the earliest years, before the members of the profession became fully aware of the need for medical associations, and for medical legislation, to protect both the laity and themselves, there was little opposition to quackery, even on the part of the otherwise intelligent. Even in the middle of the Twentieth Century, there are members of the laity who apparently enjoy wandering the bypaths of irregular therapeutics.

The sincere physicians who gave their best and sought to improve, who made their permanent homes in Mower County, served the people well and won their respect and esteem. They were true pioneers and builders. Their names head the lists of civic leaders. Not only did they practice medicine conscientiously, they served in schools and churches, on township and village boards, as mayor of city and village, and, several of them, in the state legislature.

The following tribute, paid to the early physicians in the *History of Mower County* of 1884, is timely here:

> The medical fraternity of Mower County have, with few exceptions, been an honor to the profession. They have been ready to respond to the call of duty, mid summer's intense heat and the freezing blasts of winter. Nothing could cause them to turn a deaf ear to the cry of pain and suffering. They have been compelled to cross trackless prairies, to face blizzards from the Northwest, often with no hope of a fee or reward, but only, if possible, to relieve those who pleaded for their care and advice. All this has been done by the practicing physicians of Mower County, and that without a murmur or complaint. If the good deeds of this profession are not remembered by those who have received aid and life at their hands,

through such a train of hardships, a time will come when all will be remembered. The names of such men as Drs. Wheat, Hollister, Kingsbury, Alsdorf and others are mentioned in this chapter. It is hoped that the hearts which perhaps now beat in robust health, will be touched, and that all of the pioneers will respond, "May God bless them."

One can gain a glimpse of the life the early physicians led by reading the old records, newspapers and directories. Their offices usually were upstairs over a store where they had a "waiting room" and a consulting room. Their equipment was meager and they depended greatly on their own knowledge of disease, their keen perception of the signs of disordered health, and a deep understanding of the people they served. Their treatment for disease was largely empirical. Prior to 1900 the contagious diseases of childhood were always prevalent, and diphtheria particularly accounted for many tragic deaths. A physician's reputation often hinged on his success in treating the victims of an epidemic. Accidental injuries were common, and since methods of treatment were crude, many extremities were amputated. Some surgeons pointed with pride to the number of amputations they had performed. In general, however, surgical procedures were a minor part of the doctor's work, and the operations were performed in the homes of the patients; Mower County did not have a hospital until 1896. For the most part the physician's practice consisted of care of those ill with infections and contagious disease, treatment for injuries, delivering babies, and caring for those suffering from various chronic or "hopeless" diseases. As Dr. A. E. Henslin of Le Roy remarked in his later years, "We did the best we could with what we had." No one can do more, whether it be in 1860, 1900, 1957, or 1990.

The professional cards of the early physicians, in directories and in newspapers, often carried, in addition to address, two important items: "Office hours 1 to 3 p.m." and "Calls answered promptly, Day or Night." Their office hours necessarily were short, since they spent long hours making their extended rounds with horse and buggy, or horses and sleigh in winter, to visit patients in their homes. Few sick persons were brought to the office, few well persons consulted a physician.

Dr. Oliver Wendell Holmes graphically described the old doctor's daily routine:

Half a dollar a visit—drive, drive, drive all day; get up in the night and harness your own horse—drive again ten miles in a snowstorm; shake powders out of a vial—drive back again, if you don't happen to be stuck in a drift; no home, no peace, no continuous meals, no unbroken sleep, no Sunday, no holiday, no social intercourse, but eternal jog, jog, jog in a sulky.

(To be continued in the October issue)

MINNESOTA STATE BOARD OF MEDICAL EXAMINERS

230 Lowry Medical Arts Bldg., Saint Paul 2, Minnesota

F. H. Magney, M.D.

Secretary

PHYSICIANS LICENSED FEBRUARY 20, 1959

January, 1959, Examination

The annual business meeting in the Cloud Room, presided over by Mrs. Fellows, was attended by 100 members.

Mrs. Gastineau gave a brief address, commending the Auxiliary members for their work in furthering medical careers. She said $200,000 had been given by the auxiliaries for loans and scholarships through the AMEF. Auxiliaries all over the country are increasing in membership, she said. The national president said that the major part of the annual program of auxiliaries should be the legislative program. She urged members to back the eight-point program in legislation being supported by the American Medical Association. Health legislation and the preserving of present standards is the most urgent business of the AMA, she said.

Elections Held

Mrs. Walter P. Gardner, St. Paul, is the 1960-61 President; Mrs. W. A. Merritt, Rochester, President-Elect; Mrs. M. I. Hauge, Clarkfield, First Vice President; Mrs. Karl Anderson, Minneapolis, Second Vice President; Mrs. H. M. Carryer, Rochester, Third Vice President; Mrs. M. M. Howell, Glencoe, Recording Secretary; Mrs. Wallace Gleason, St. Paul, Corresponding Secretary; Mrs. Elmer Hill, Minneapolis, Treasurer; Mrs. Karl Johnson, Duluth, Auditor; Mrs. Charles Waas, St. Paul, Historian; and Mrs. M. F. Fellows, Duluth, Parliamentarian.

Officers had been elected at the business meeting prior to the luncheon. They were installed by Mrs. A. J. Bianco of Duluth, a past president. Mrs. Bianco in officiating, admonished the new officers to "bear in mind that the main objective of this organization is to direct public thinking and actions in channels the medical profession desires and to extend authentic information on health."

About 175 women attended the luncheon, which was presided over by Mrs. M. F. Fellows, Duluth, retiring President, and attended by several special guests, including Mrs. Frank Gastineau and Mrs. Rolf Charlston, Oak Park, Illinois, daughter of Dr. Clarence Jacobson, Chisholm, President of the Minnesota State Medical Association.

Mrs. Gardner made a brief speech of acceptance of her office and Mrs. H. F. Polley, convention co-chairman with Mrs. D. C. Dahlin, introduced the guest speaker, Mrs. Lynn Pontious, of Minneapolis.

Past presidents honored at the luncheon were Mrs. M. A. Nordland, Minneapolis; Mrs. J. F. Norman, Crookston; Mrs. F. S. McKinney, Minneapolis; Mrs. Charles Waas, St. Paul; Mrs. C. L. Oppegaard, Crookston; Mrs. Reuben Erickson, Minneapolis; Mrs. H. E. Bakkila, Mrs. F. J. Elias and Mrs. P. S. Rudie, Duluth; and Mrs. Hammes.

The Auxiliary members concluded their thirty-eighth annual meeting when they attended a coffee at the home of Mrs. Polley with Mrs. Dahlin as co-hostess. Tuesday evening, they joined their husbands at the annual banquet of the medical group in the Kahler Hotel.

. . . the formation of vitamin A, fibrinogen, heparin, prothrombin; the storage of glycogen, iron, copper; the metabolism of carbohydrates, proteins and lipids, etc. The importance of maintaining normal liver function— and its repair when damaged—is readily apparent.

methischol®

choline, methionine, inositol, vitamin B_{12}, desiccated liver

METHISCHOL:
capsules: 100, 250, 500, 1000;
syrup: 16 oz. and 1 gallon

Samples of METHISCHOL and literature available from

u. s. vitamin & pharmaceutical corporation
Arlington-Funk Laboratories, division
250 East 43rd Street, New York 17, N. Y.

helps restore or maintain liver normality when hepatic damage occurs or threatens in

cirrhosis
alcoholism
hepatitis
obesity
diabetes
atherosclerosis

Methischol acts to remove hepatic fat, stimulate regeneration of new functioning liver cells, and lessen tendency to fibrosis and cirrhosis.

In Memoriam

ROBERT M. BURNS

Dr. Robert M. Burns, a practicing physician in St. Paul for more than fifty years, died in St. Joseph's Hospital, June 6, 1960. He was eighty-one years of age at the time of his death.

Doctor Burns had served on the staffs of most St. Paul hospitals through the past fifty years.

He was born in Danville, Wisconsin, and was graduated from the University of Minnesota Medical School in 1906. He served his internship at St. Luke's Hospital in St. Paul.

In the early years of his medical career, he practiced with two well-known men, the late Dr. C. E. Riggs and Dr. C. R. Ball, in psychiatry and ailments of the nervous system. Later he joined the Earl Clinic where he was associated for many years.

Doctor Burns was a past president of the Ramsey County Medical Society and a life member of the Minnesota State Medical Association. He also belonged to the American Medical Association, the Lion's Club, and the Knights of Columbus.

He is survived by his wife, Mary; a son, Robert M.; a daughter, Mrs. Helen M. Barron; a brother, John A. Burns, all of St. Paul, and seven grandchildren.

NORMAN E. FIDELMAN

Doctor Norman E. Fidelman, Foley physician, died April 22, 1960, at the age of thirty-five.

Born in Minneapolis, Doctor Fidelman was a 1947 graduate of the University of Minnesota Medical School. He had practiced in Foley for twelve years.

Doctor Fidelman was a member of the Stearns-Benton County Medical Society, the Tri-County Medical Association, the Minnesota State Medical Association and the American Medical Association. In addition he belonged to the Phi Delta Epsilon Medical Fraternity and was president of the Central Minnesota Chapter of the American Academy of General Practice.

He was a staff member of the St. Cloud Hospital and also was a member of B'nai B'rith, Tifereth B'nai Jacob synagogue and United Hebrew Brotherhood.

Doctor Fidelman formerly served with occupation forces in Europe as a captain in the army medical corps.

Survivors include his wife, Marian; three sons, Robert Allen, David Michael and Joseph Aaron; a daughter, Marilyn; his father, Louis Fidelman, Minneapolis; and two sisters, Mrs. Molly Ackerman and Mrs. Frieda Berezovsky, both of Minneapolis.

COMPLETE LABORATORIES CONVENIENTLY LOCATED IN UPPER MIDWEST CITIES

CONSISTENTLY GOOD CLINICAL RESULTS IN TRICHOMONAL AND MONILIAL VAGINITIS

TRICOFURON IMPROVED (Suppositories and Powder) cured 143 of 161 patients with vaginitis due to Trichomonas vaginalis, Candida (Monilia) albicans, or both. "Almost immediate symptomatic improvement was noted with the first insufflation."

Criteria for cure: freedom from infecting organisms as well as symptoms on repeated examinations during a three-month follow-up. This cure rate of 88.8% is "surprisingly similar" to results reported by earlier investigators.

Coolidge, C. W.; Glisson, C. S., and Smith, A. S.: J.M.A. Georgia 48:167, 1959.

TRICOFURON®

IMPROVED

2-step treatment brings swift relief, eradicates stubborn trichomonads, Candida (Monilia) albicans, Hemophilus vaginalis

1. POWDER for weekly insufflation in your office. MICOFUR®, brand of nifuroxime, 0.5% and FUROXONE®, brand of furazolidone, 0.1% in an acidic water-dispersible base.

2. SUPPOSITORIES for continued home use —1st week one suppository in the morning and one on retiring. After 1st week, one suppository at night may suffice.

Continue use of suppositories during menses. Treatment should be continued throughout a complete menstrual cycle and for several days thereafter. MICOFUR 0.375% and FUROXONE 0.25% in a water-miscible base.

Rx new box of 24 suppositories with applicator for more practical and economical therapy.
Also available:
box of 12 suppositories with applicator.

NITROFURANS—a *unique* class of antimicrobials
EATON LABORATORIES, NORWICH, NEW YORK

Here's the BIG news in professional liability insurance –

NO ADDITIONAL PREMIUM FOR PARTNERSHIP COVERAGE

and NO EXTRA PREMIUM FOR COVERAGE OF EMPLOYED PHYSICIANS OR TECHNICIANS

All other malpractice policies have an additional charge of 20 per cent or more of the individual rate to provide partnership coverage. Additional charges are also made in other policies by reason of the employment of other physicians, surgeons, x-ray or laboratory technicians. **Physicians & Surgeons Underwriters Corporation makes no additional charge for such coverage.** "Physicians & Surgeons" is administered by a medical Board of Directors. It is the FIRST COMPANY in Minnesota to offer this partnership and group practice feature, plus a rock bottom basic premium structure and a new broad comprehensive policy.

There are many other features in the Physicians & Surgeons policy that are built in for the protection of the doctor. Write or call today for complete details on this all-risk comprehensive policy.

ELMER J. LILLEHEI

Dr. Elmer J. Lillehei, Robbinsdale physician for thirty-four years, died May 14, 1960. Doctor Lillehei was sixty-five years of age at the time of his death.

Doctor Lillehei was born in Sioux City, Iowa, and was graduated from the University of Minnesota Medical School in 1925.

He was a member of the medical fraternity, Psi Chapter of Alpha Kappa Kappa, past master of Compass Masonic Lodge Number 265 of Robbinsdale and a past patron of the Eastern Star. Doctor Lillehei also belonged to the Minnesota Pathologic Society, the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. He was a veteran of World War I and a member of the Westphal American Legion Post.

Doctor Lillehei is surived by his wife, Ann; a daughter, Mrs. Donald (JoAnn) Wold, Brooklyn Park; a son, Roger, Brooklyn Park; his mother, Mrs. Paluda Larson, Minneapolis, and a brother, Dr. Clarence I. Lillehei, Minneapolis.

JAMES H. McCLANAHAN

Doctor James H. McClanahan, White Bear Lake physician, died April 14, 1960, at the age of seventy-seven.

He was born in Kirkwood, Illinois, and was graduated from Northwestern Medical School in 1909. Practicing in Ely, Minnesota, for three years, he came to White Bear Lake in 1913, where he became a staff member of St. Johns Hospital. He retired from active practice in 1951.

He was a member of the Ramsey County Medical Society, a life member of the Minnesota State Medical Association and the American Medical Association. In addition he was a member of the Lions Club of White Bear Lake.

Survivors include two daughters, Mrs. Burton Wheatlake, Denver, Colorado; and Mrs. John Hager, Ormond Beach, Florida; a son, Richards of Worthington, Ohio; a sister, Miss Helen McClanahan, Knoxville, Illinois; and two brothers, Dr. T. Scott McClanahan, White Bear Lake, and Ralph, Monmouth, Illinois.

The Physician's Diary

The Board of Directors of the Minnesota Alumni Association has presented to **Dr. Lillian L. Nye**, St. Paul, an award in recognition of fifty years of loyalty to the University of Minnesota. The title of Graduate Emeritus was bestowed upon Doctor Nye.

* * *

By an invitation from Governor Orville Freeman, **Dr. G. N. Getman, Luverne,** attended two conferences on children and youth. Doctor Getman was also invited to participate in the first statewide Governor's Conference on Rehabilitation.

* * *

Dr. A. O. Swenson, Duluth, was guest speaker at the Annual Past Master's Night Program sponsored by Euclid Masonic Lodge in the Euclid Temple. Doctor Swenson is a past master of the Euclid Lodge.

* * *

Mayo Clinic staff member, **Dr. George B. Logan**, was in charge of a forum on health, fitness and safety of youth at Governor Freeman's 1960 Biennial Governor's Conference on Children and Youth. Also attending the Conference was **Dr. John S. Pearson.** Doctors Pearson and Logan were delegates to the 1960 President's Conference held April 1 and 2, in Washington, D. C.

* * *

Crookston physician, **Dr. D. A. Peterson**, presided over the meeting of the Minnesota Academy of Foot Surgeons. **Dr. John L. Falls**, Red Wing, spoke on the Forand Bill.

* * *

Some forty physicians from Minnesota, Iowa, and Wisconsin met recently in Rochester for an organizational meeting of the Upper Midwest Allergy Society. Among fifteen papers presented at the meeting were those by **Dr. Kinsey Simonton** and **Dr. G. A. Peters** of the Mayo Clinic. A tour of the Mayo Clinic followed. Physicians making arrangements for the meeting were **Doctors L. L. Henderson, G. A. Peters, Giles A. Koelsche, Haddon Carryer, L. E. Prickman** and **George B. Logan.**

* * *

Dr. Eugene Kuz, formerly of St. Paul, is now associated in a partnership practice with **Dr. B. G. Pearson** of Shakopee. Doctor Kuz previously was in private practice of obstetrics and gynecology with the late **Dr. James S. McCabe.**

* * *

"People Speak in Many Ways" was the title of the talk given by **Dr. Paul Wilson**, Director of the Olmsted County Mental Health Clinic, at the opening session of an Institute on Communications in Public Health at the University of Minnesota Center for Continuation Study.

* * *

Dr. Edward A. Banner, Mayo Clinic, has taken over as President of the Minnesota Obstetrical and Gynecological Society at its Annual Meeting in Rochester. Other officers include **Dr. Charles H. McKenzie**, Vice President and **Dr. Alex Barno**, Secretary-Treasurer, both of Minneapolis.

Mayo Clinic staff member, **Dr. Waltman Walters**, has been elected a corresponding member of the German Surgical Society. The election took place at a recent meeting of the organization in Munich, according to information received from Dr. Willi Felix, of Berlin, President of the Society. The election of Doctor Walters to corresponding membership was unanimous.

* * *

Dr. Charles Mayo, Rochester, as a member of the Board of Directors of Mutual of Omaha, announced that the insurance company will erect a model nursing home in Washington, D. C., which will be used to try and solve the health problems of the aged.

* * *

The subject of the Shakopee Profile, a feature in the **Shakopee Valley News**, was the life of **Dr. B. F. Pearson.** The feature began with Doctor Pearson's decision as a small boy to become a medical doctor and followed through his many activities today.

* * *

Over 900 residents of Grant county and the surrounding area gather together to honor **Drs. Lester R. and Lillian B. Parson** for their thirty-six years of tireless service. The program was a complete surprise to Doctor Lester because of the close cooperation of his wife, Dr. Lillian Parson with the program planning committee. Mrs. Parson, who thought the program was entirely for her husband, was in turn surprised when the sign on the stage was changed from "Dr." to "Drs.", and she was informed that she was also being honored.

* * *

Two Minnesota physicians will play leading roles at the Third Congress of International Federation of Physical Medicine Meeting in Washington, D. C., August 21-26. **Dr. Frederic J. Kotke**, Professor and Head of the Department of Physical Medicine and Rehabilitation, University of Minnesota Medical School, is president of the American Congress of Physical Medicine, Host Organization for the Third International Congress. **Dr. Frank H. Krusen**, Director of Physical Medicine and Rehabilitation at Mayo Clinic, is President of the Third International Congress. Bernard M. Baruch, financier and adviser to several United States Presidents, will speak at the Congress.

* * *

Dr. Thomas G. Murn has been named to replace **Dr. Edward LaFond**, both of St. Cloud, as city physician. Doctor Murn has been deputy health officer, assisting the city physician since January.

* * *

The medical assistance bills for the aged now before Congress are out-and-out vote getting measures, **Dr. Laurence D. Hilger** told the Midway Lions Club Luncheon Meeting in May. Doctor Hilger spoke as a representative of the Ramsey County Medical Society.

For fast, complete treatment of vaginal infections

Problem is: she'll wait until discomfort is acute and then expect immediate relief. The answer is Trisert. Trisert preparations contain ALLANTOIN, an effective debriding agent which quickly dissolves heavy mucus often accompanying vaginal infections . . . METHYLBENZETHONIUM CHLORIDE, a quaternary germicide which removes unpleasant odors . . . SUCCINIC ACID, an aid in maintaining optimal vaginal pH . . . 9-AMINOACRIDINE HYDROCHLORIDE which has been included to supplement the bactericidal and trichomonacidal activity of other constituents. Treatment with Trisert Powder will control symptoms fast . . . usually within an hour . . . and provide effective initial treatment for 48 hours. After a second insufflation, the treatment is completed with at home use of Trisert Tablets which will generally bring the infection under complete control within 7 days.

Trisert

TRISERT TABLETS—Patient set, contains bottle of 30 tablets and special inserter. Bulk bottle of 100 tablets.

TRISERT POWDER—Available in 4 gr. individual treatment bottles. 12 to carton.

TRISERT POWDER INSUFFLATOR—Designed for use with Trisert Powder. Its use is urged for maximum efficiency.

* * *

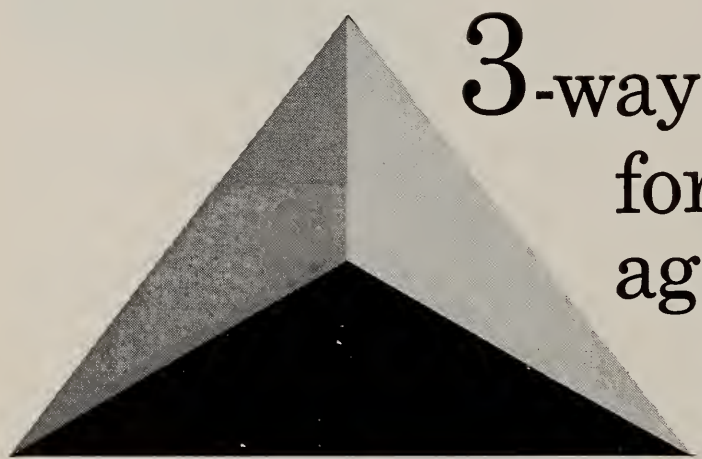
The Northern Association for Medical Education has set a goal of $28,000. The announcement came from **Dr. Jane E. Hodgson,** Chairman of the Finance Committee of the Association.



Book Reviews

Books listed here become the property of the Ramsey, Hennepin and St. Louis County Medical Libraries when reviewed. Members, however, are urged to write reviews of any or every recent book which may be of interest to physicians.

ORTHOPEDIC SURGERY IN THE MEDITERRANEAN THEATER OF OPERATIONS. By Oscar P. Hampton, Jr., M.D., F.A.C.S., Colonel, MC, USAR. (U. S. Army. Surgeon General's Office. The Medical Department of the U. S. Army in World War II) 368 pages. Illus. Washington, D. C.: Government Printing Office, 1957. Price, $4.00.

Every orthopedic surgeon will profit from the study of this excellent volume depicting the experiences had in dealing with fractures in World War II. Of particular value is the discussion of the treatment of massive compound fractures and the use of internal fixation in the face of compounding of fractures. Injuries of the joints are very capably discussed and well illustrated. The volume is profusely illustrated with excellent reproductions of x-rays, well selected photographs and illustrative drawings. No better hand volume can be recommended for the surgeon who deals with trauma.

when pollens harry the unwary

BENADRYL®

antihistaminic-antispasmodic

gives prompt, comprehensive relief

In hay fever, BENADRYL provides simultaneous, dual control of allergic symptoms. Nasal congestion, lacrimation, sneezing, and related histamine reactions are effectively relieved by the *antihistaminic action* of BENADRYL. At the same time, its *antispasmodic effect* alleviates bronchial and gastrointestinal spasms. This duality of action makes BENADRYL valuable throughout a wide range of allergic disorders.

BENADRYL Hydrochloride (diphenhydramine hydrochloride, Parke-Davis) is available in a variety of forms including: Kapseals,® 50 mg. each; Kapseals, 50 mg., with ephedrine sulfate, 25 mg.; Capsules, 25 mg. each; Elixir, 10 mg. per 4 cc.; and for delayed action, Emplets,® 50 mg. each. For parenteral therapy, BENADRYL Hydrochloride Steri-Vials,® 10 mg. per cc.; and Ampoules, 50 mg. per cc.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Minneapolis, Minnesota

From the Department of Surgery, University of Minnesota Medical School, Minneapolis 14, Minnesota. Supported in part by USPHS Grant No. RG5221.

HYPNOSIS is among the oldest of the medical arts and traces its origin to the times of the ancient Greeks. Indeed, the priest-physicians in the temples of Aesculapius practiced what is closely akin to modern hypnotherapy. Since then, it has enjoyed sporadic bursts of popularity only to fall back into disrepute as exaggerated claims by charlatans were disproved. In the eyes of many, hypnosis is synonomous with the antics of the stage performer. In spite of this, it is currently enjoying a rebirth, and it is the purpose of this paper to examine critically the results of hypnotherapy in 260 patients treated over the past three and one-half years in a variety of surgical states.

Methods and Results

Hypnoanesthesia for Proctoscopy.—Proctoscopy is in too many patients a source of embarrassment and pain, owing chiefly to ignorance and superstition. Yet, it remains a standard technique in diagnosis and examination of the rectum and lower bowel and is the *sine qua non* in the early diagnosis of rectal cancer. Thus it is within the physician's province to provide a suitable means of allaying the fears of the layman regarding this important adjunct. Hypnosis has proved a most worthy and acceptable tool.

To date, seventy-two patients have received the benefit of hypnoanesthesia for proctoscopy. Fifty-seven of this group had undergone previous proctoscopy and considered it to have been a painful experience, while the remaining fifteen patients were experiencing the procedure for the first time. Our method has been to induce the hypnotic state prior to examination and to make suggestions relative to the ease and painlessness of the procedure, and to instill in the patient a spirit of cooperation. The patient is then awakened and the examination is made immediately. The results are shown in Table I.

TABLE I. HYPNOANESTHESIA FOR PROCTOSCOPY

Results	Previous Experience		No Previous Experience	
	Number of Patients	Per Cent	Number of Patients	Per Cent
Excellent	37	64.9	10	66.7
Good	12	20.1	2	13.3
Fair	4	7.0	1	6.7
Poor	4	7.0	2	13.3
Total	57	100.0	15	100.0

All evaluations were based on comments made by the proctologist and nurse in attendance and by the patients themselves. For a patient to be classified as an excellent result, the patient had to report little or no discomfort or pain during the examination, and the proctologist and nurse made a notation of the excellence of the patient's behavior, as well as the adequacy of the examination. A good result indicates an adequate examination with only slight discomfort to the patient, while a fair result implies a less satisfactory ex-

amination with moderate discomfort. A poor result indicates an unsatisfactory examination, with considerable pain and aggravation displayed by the patient. It was felt that by selecting patients who already had some experience with

TABLE II. CONTROL OF POSTOPERATIVE PAIN BY HYPNOSIS

Comparison of Narcotic Doses

*Hypnotherapy eight to twenty-four hours prior to surgery.
**Hypnotherapy during induction of anesthesia immediately prior to surgery.

the procedure, there was established a standard of comparison. In addition, no patient with previous experience was considered a good or excellent result if he felt that hypnosis was ineffective in reducing the discomfort experienced on prior examinations. Among this group were several patients who earlier had received narcotics, as well as one patient in whom general anesthesia was necessary for a previous proctoscopic examination. Such measures were obviated completely by the use of hypnosis, and in the two groups, 80 per cent experienced a good or excellent result attending induction of the hypnotic state immediately prior to performance of the examination.

D. C., an eighteen-year-old girl with a four-year history of severe recurrent bloody diarrhea, had undergone proctoscopy on two previous occasions. These examinations had been attended with such pain and displays of emotion by the patient that it had been necessary to terminate the procedure and administer narcotics. When first seen on this admission, this same patient refused to permit a rectal examination to be done. Because of the necessity of establishing a diagnosis, it was decided that a repeat proctoscopy should be done. Immediately prior to this examination, the patient was placed in the hypnotic state and then a satisfactory proctoscopy was carried out without any pain or emotional display by the patient. No narcotics were required. A diagnosis of chronic ulcerative colitis was made and subsequently a total colectomy, proctectomy, and ileostomy were performed.

Postoperative Pain.—In spite of the tremendous advances in surgery, pitifully little has been done to make the memory of operation more pleasant for the patient. Witness the fear and anxiety with which the patient greets the news that he must have surgery. In spite of the high degree of safety, the layman has not changed his attitude regarding the surgeon and operation. Thus, it is our feeling that hypnosis has a very definite place in the control of postoperative pain.

We have pre-treated eighty-five patients who were about to undergo major abdominal and thoracic surgery by hypnotic suggestion, in an effort to allay the anticipated discomfort of the postoperative period. Members in this group have been treated in one of two ways: In the first group of sixty-eight patients (Table II), hypnotherapy was given the day prior to operation, and suggestions imparted relating to tolerance of indwelling nasal tubes and urinary catheters and the acceptance of intravenously-administered fluids, suggesting to each patient that none of these will occasion distress. It is also suggested to these patients that the area of incision will cause no discomfort; an attempt also is made to instill in the patient a sense of confidence in the success of the procedure and a spirit of cooperation with members of the nursing and surgical staff. Finally, all patients are told that analgesics are available and will not be withheld when needed. In the second group of seventeen patients (Table II), hypnotherapy was given on the operating table just prior to and during the anesthesia-induction period. The same suggestions were made to both groups of patients. The observed results are recorded in Table II in which the narcotic requirements of the treated groups are compared; a group of untreated controls selected at random, undergoing similar operations, also was employed for purpose of comparison.

While it is difficult to evaluate the benefits derived by the treated group due to the subjective nature of pain, the reduction in the amount of narcotics required by the treated groups is obvious (38.7 per cent). It would appear that narcohypnosis may be an even more potent agent than the conventional techniques of hypnotherapy and we intend to explore this variant further. It may be that a combination of the two methods may be more effective than either alone. In addition, there appeared to be a greater buoyancy of spirit, better cooperation, and fewer complaints in the treated groups, than in the untreated group.

A better appreciation of the results may be obtained by considering that six patients under-

going cholecystectomy by the same surgeon, four treated patients received none, one, two, and four doses of narcotic after surgery, while two untreated patients received eight and eleven doses of the same agent. In addition, four patients underwent "second-look" procedures for residual carcinoma after the removal of the primary lesion and received hypnotic suggestion prior to the second procedure only. In this group, there was an average reduction of narcotics after the second operation to only 12.8 doses, as compared to 35.5 after the initial procedure.

Mrs. M. D., a fifty-two-year-old white woman, underwent a panhysterectomy and bilateral salpingo-oöphorectomy for carcinoma of the ovary in August 1958. During convalescence she required a total of forty doses of demerol. A second-look procedure was carried out in May, 1959, after previous hypnotherapy the evening before the operation. Following the second procedure, a total of only three doses of demerol was required. The patient was much more cheerful and enthusiastic; she ambulated earlier, and was generally a much more pleasant and cooperative person.

Miscellaneous Types of Pain.—Pain is one of the most frequent presenting complaints of patients. For some conditions, the physician must be content with palliation and relief of pain, foregoing the more desirable objective of elimination of the cause. Still, there is no universally effective analgesic available and there are many situations which try the soul of both patient and physician in regard to pain. Most notable among these are the conditions of metastatic cancer, phantom limb, the various neuralgias, and arthritides.

We have treated forty-six patients with hypnotherapy for various painful states and all have been followed three months or longer and have been available for evaluation. Our method of treatment in this group is to induce the hypnotic state, at which time suggestions are made relative to anticipated relief of pain. In a few instances, the patients were taught self-hypnosis, but in no patients was psychologic evaluation made. The patients were seen at weekly intervals until maximal benefit had been obtained and then reassessed periodically thereafter. Between two and ten weekly sessions were necessary to obtain good or excellent results, with an average of four. Invariably in patients who failed to secure satisfactory relief, the patient usually terminated the therapy after four to six sessions. Patients in whom good or excellent results were achieved have been followed for periods varying between three and thirty-two months (average 14.8 months) or until the time of death, as the case may be. Because of the subjective nature of pain, several criteria have been established to help determine what constitutes a good or excellent result: (1) complete elimination or marked reduction in narcotic requirements contrasted with the situation prior to therapy, (2) hypnotherapy succeeded in achieving pain relief in patients to whom chordotomy had been proposed, (3) the patient reports only minimal and no persistent symptoms, (4) relief persists until the time of death or at least three months without permanent recurrence. A fair result indicates only mild amelioration of symptoms; a poor result denotes no improvement or failure to achieve the objective. The observed results are shown in Table III.

TABLE III. MISCELLANEOUS PAIN

Type of Pain	Results			
	Excellent	Good	Fair	Poor
Metastatic CA	2	3*	4	3

Neuralgia	1†	—	2	1
Unclassified pain	2	—	—	4
Total	13	8	10	15

*Cordotomy avoided in one patient.
**Prior failure of cordotomy.
†Prior failure of trigeminal rhizotomy and avoidance of glossopharyngeal rhizotomy.

In one instance, cordotomy was avoided, while in two cases hypnosis resulted in marked relief after failure of cordotomy and trigeminal rhizotomy respectively. Thus, a good or excellent result was obtained in twenty-one of forty-six patients (45.7 per cent), and in no patient was a recurrence of symptoms noted which failed to respond to further therapy. Several patients, however, experienced occasional mild exacerbation of symptoms but these were easily controlled with further therapy.

Mrs. G. G., a fifty-five-year-old white woman, underwent resection of a sphenoid ridge meningioma in 1947 following which she was partially aphasic. In 1958, she began to complain of severe facial pain and a trigeminal rhizotomy was carried out. No recurrence of the tumor was noted but no relief of pain was achieved and soon the patient began taking narcotics. The drugs gave only minimal relief, and a glosso-pharyngeal rhizotomy was proposed. However, a course of hypnotherapy prior to further surgery was decided upon. Because of the

problem of the aphasia, it was necessary to utilize narcohypnosis. Following this, the patient was seen on two subsequent occasions at which time hypnotherapy was carried out by the usual means in the absence of any drugs. Since then, the patient has eliminated the use of narcotics and operation has been avoided; she has had only minimal symptoms during a period of more than one year since hypnotherapy was used.

Postgastrectomy Syndrome.—There can be little doubt that the dumping syndrome is the most perplexing complication attending gastric resection for duodenal ulcer. It has been a common observation that patients developing this complication fit a certain personality pattern. It may well be that the operation merely serves to focus attention on the operated stomach and without it, these patients would have other equally bizarre complaints. Sooner or later the physician and surgeon are forced to admit defeat in a great proportion of these cases. We have found hypnosis useful in the treatment of this vexing problem.

Forty-one patients suffering from the postgastrectomy dumping syndrome have been treated during the past three and a half years. Only patients subjected to gastric resection longer than one year prior, were accepted for treatment. It is well known that many patients exhibit typical dumping symptoms immediately after surgery, but these disappear in a few months. All types of gastric resection are represented in this study, the Billroth II operation predominating. Our method of therapy has been to aim hypnotherapy directly at the removal of the patient's specific complaints. Sessions are held at weekly intervals until an optimal result is obtained, with periodic reappraisal therafter. Between two and twenty-one inductions were necessary to achieve an optimal result (average 5.6). The follow-up on these patients ranges from four to forty-three months, with an average of 25.2 months. Only four patients have been followed less than one year, and twelve patients have been followed over three years. The remainder (twenty-five patients), have been followed from one to three years. Objective evidence of weight gain, in addition to the patient's statement regarding the degree of relief from symptoms, was employed to characterize as good or excellent the observed results. A fair result indicates only symptomatic improvement without weight gain; a poor result suggests that neither objective was achieved. The observed results are recorded in Table IV.

TABLE IV. POSTGASTRECTOMY SYNDROME

Results	Number of Patients	Per Cent Total	Average Weight Gain (Pounds)
Excellent	16	39.0	7.8
Good	10	24.4	7.1
Fair	3	7.3	—
Poor	12*	29.3	—
Total	41	100	—

*Includes four patients who had remission after excellent symptomatic relief and weight gain for over one year.

It can be seen that good and excellent symptomatic relief and weight gain was experienced by 63.4 per cent of the group. Only four patients suffered a permanent recurrence of symptoms to the level of the initial complaint and all had more than a year's relief.

Mr. L. A., a fifty-two-year-old unmarried man, underwent gastric resection in 1955 for peptic ulcer. Since then he had been plagued with severe dumping symptoms to the extent that he was 40 pounds below his preoperative weight. Hypnotherapy was begun in November, 1956, and after eleven sessions, he was nearly completely free of symptoms. Since his first visit, he has gained 20 pounds and at the present time, almost three and a half years later, the patient continues to maintain an excellent asymptomatic state.

Obesity.—The problem of obesity has presented itself to the general physician, surgeon, and psychiatrist alike, and none have met with great success. In spite of the numerous articles in the lay press warning of the hazards of obesity, dieting is nevertheless a severe test of the body. In an effort to create a more fertile soil in which to implant the seed of caloric reduction, we have embarked on a program of combined hypnotherapy and caloric reduction.

Sixteen obese patients have been treated with hypnotherapy in an attempt to enforce dietary restriction. The method employed has been to place the patient on a strict reducing diet, encouraging the patient by suggestion to accept the dietary restrictions. When possible, the patients are seen weekly thereafter, at which time the procedure is repeated.

A glance at the results in Table V reveals that all of the sixteen patients treated discontinued therapy after varying intervals and at that point, none had even approximated an ideal weight. Further, most patients failed several appointments during therapy. These results are far from encouraging and do not augur well for the promise of hypnotherapy in the management of obesity.

Discussion

Previous reports from this clinic have documented our earlier experience with hypnotic suggestion as a mode of therapy for a number of conditions which relate to the surgeon's activity.

TABLE V. OBESITY

Case No.	Initial Weight	Weight Loss	No. of Weeks	No. of Sessions	Result	Remarks
1-7	195-239	—	—	1	Poor	Patient terminated
8	175	15	52	8	Fair	"
9	165	30	18	2	Fair	"
10	237	30	17	8	Fair	"
11	213	15	88	8	Fair	"
12	204	13	4	3	Fair	"
13	276	16	3	2	Fair	"
14	197	18	65	13	Fair	"
15	232	25	18	12	Fair	"
16	200	14	9	6	Fair	"

A comparison of the results obtained indicates certain discrepancies. Our initial studies 1-4 concerned the postgastrectomy dumping syndrome and earlier results indicated a slightly higher incidence of improvement than that reported herein. However, as this work has progressed, we have begun to treat a more unfavorable group of patients in that they have not presented characteristic symptoms of the "dumping syndrome" but a variety of bizarre complaints attributed to gastrectomy. No doubt, many of these newer patients have deeper psychologic problems with which mere symptom removal cannot cope. Nevertheless, a sufficient number of this group achieve a worthwhile result, such that we are encouraged to continue use of hypnotherapy in this latter group. It is interesting to note that less than 10 per cent of the group has had recurrence of complaints, so that it would appear that mere symptom removal can, indeed, produce long-term results.

As we have continued our efforts in the alleviation of postoperative pain by hypnosis, we are more impressed than ever that this is a worthwhile adjunct. As more experience has been gained, the narcotic reduction in the treated group has increased with the result that we are now applying this method to thoracotomy and more extended abdominal procedures than before. Especially encouraging are the results obtained in the small group undergoing "second look" procedures.

The group undergoing proctoscopy has been a most satisfying venture to all concerned, with the result that patients now request therapy, having heard of its dramatic results from a fellow patient or friends. One of our proctologists has been so impressed with the greater ease and facility of sigmoidoscopic examinations under hypnotherapy that he is adding it as a preliminary adjunct to the procedure in his private practice.

The results obtained in the group of patients suffering from a miscellany of pains are somewhat difficult to rationalize and understand. In the phantom limb group, results have been uniformly good, while in the other groups, only fair. It is especially mystifying, since in all other groups an occasional dramatic result has occurred, with avoidance of operation and discontinuance of narcotics. It may be that those suffering from the phantom limb are merely more susceptible to hypnotherapy. Be that as it may, the occasional good result obtained in patients complaining of bizarre types of pain is impressive enough to warrant continuation of hypnotherapy in the group as a whole.

Our results in the use of hypnosis as an adjunct to weight reduction continue to be discouraging. It would appear that this method has little to recommend itself. Our impression is as before, that many of these patients have unexpressed psychologic problems and obesity is merely an expression thereof.

Summary

1. The use of hypnotherapy in 260 patients in a variety of surgical states has been reviewed.

2. This method has proved to be of great value in relief of the discomforts of proctoscopy, postoperative pain, and the postgastrectomy syndrome.

3. Hypnotherapy is invaluable in relief of phantom limb pain, and has occasionally been found useful in a wide variety of other painful states.

4. Hypnotherapy has not been a successful mode of management in obesity.

The Cytologic Diagnosis of Cancer

A Practical Approach for the Practicing Physician

"Every physician's office can be a cancer-detection center" is a modern apothegm that emphasizes a tremendous potential in the cure of cancer. This article dispassionately dissects the role of cytologic techniques in cancer detection, assessing their advantages and properly weighing their limitations. It covers practically every part of the body that can shed cells for the cytologist's slides. Every physician will find much gold in this hill.

IT IS my intention to discuss my philosophy regarding the use of exfoliative cytology in the diagnosis of malignant tumors in the general practice of medicine. It is not the purpose of this communication to review the hundreds of articles pertaining to exfoliative cytology of body fluids and secretions that have mushroomed during the past fifteen years, but rather to offer a summary of the methods as applied to practically every organ system of the human body and a critique of the practical application to the practice of medicine.

The diagnosis of cancer by cytologic means as opposed to the morphologic approach is not a new method in oncology. For many years, this concept has been applied successfully in the use of fresh frozen sections. It also has enjoyed rather widespread acceptance in the examination of pleural and ascitic fluid for malignant cells, with a somewhat more limited application in the use of aspiration smears as a means of tumor biopsy.

Following the scholarly and well-received work of Papanicolaou and Traut,[1] in 1943, the postwar years were seething with enthusiasm for exfoliative cytologic diagnoses. To quote Dockerty,[2] "Every conceivable body orifice was swabbed, scraped, washed, siphoned, aspirated, brushed and massaged for its maximal yield of cells, some of which might be malignant."

The rationale of exfoliative cytology is based on the desquamation of viable cancer cells from malig-

Read at the meeting of the Minnesota State Medical Association, Rochester, Minnesota, May 23 to 25, 1960.

From the Section of Surgical Pathology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

nant tumors having a free surface. These exfoliative cells may be collected in whatever medium they lie, such as sputum, gastric washings, and vaginal secretions, stained by several methods and studied for the characteristics of malignancy.

At first glance, it would appear as if this method would be foolproof and that its application would be unlimited. Unfortunately, however, a number of restricting factors play an important role in narrowing the judicious application of the method. These include (1) the anatomic location of the lesion, (2) the presence of a free tumor surface for the exfoliation of viable cells, (3) the nature of the medium in which these cells are shed, (4) satisfactory collection and representative sampling of the exfoliated cells, and (5) interpretation of the material at hand in situations that allow histologic confirmation.

Before we embark on a discussion of specific cytologic methods, let us inquire into what we may expect to accomplish. Are we proposing a screening method for a large number of patients, or are we applying it to a selected group of patients as a diagnostic tool of a high degree of accuracy, or is it to be an adjunct to already established diagnostic methods? One should keep in mind the limitations of the cytologic methods of diagnosis and fully appreciate the significance of negative, suspicious and positive results. Probably the best approach to an evaluation of the various cytologic methods is to review the various organ systems with respect to their potential in the cytologic diagnosis of cancer.

Uterine Cervix

The most successful application of the cytologic technique has been in the detection of preclinical carcinoma of the uterine cervix. The ease with which satisfactory material for cytologic examination can be obtained and the relative accessibility of the uterine cervix to complete biopsy procedures has resulted in widespread acceptance of the cytologic method for discovering early malignant disease in this organ. In addition, the method

adapts itself readily to a screening program for large numbers of asymptomatic women.

A few simple rules should be kept in mind when one obtains cytologic material from the cervix. Since carcinoma has been observed to begin at the squamocolumnar junction in nearly 100 per cent of cases, a more nearly complete sampling of the surface epithelium by the use of a spatula to detach the surface cells of the junctional zone of the endocervix and portio is highly recommended. Care to shape this spatula so that it will fit the external os ensures more adequate sampling of the zone in question. It is imperative that the smeared material be immersed immediately in a fixative* in order to eliminate cellular distortion resulting from drying.

The literature is replete with reports on the value of cervical cytology. However, a short summary of the experience of our group at the Mayo Clinic[3,4] with this method during the past twelve years serves to emphasize its values and its limitations.

During the years 1948 through 1959, a total of 139,503 women have received a primary screening smear at the clinic. The rate of discovery of preclinical carcinoma in this group is 7.1 per 1000 women screened. These women were judged to have a normal cervix or some benign lesion of the cervix when the initial smear was taken. Of the 987 preclinical carcinomas discovered during this period, 90 (9 per cent) were infiltrating squamous cell carcinomas. It is not our policy to request cervical smears in cases of clinically suspected or diagnosed carcinoma of the cervix, as we believe that the smear should be used as a screening tool to select those cervices for biopsy which otherwise might be considered normal or to contain an inconsequential lesion.

The incidence of falsely negative results cannot be determined for obvious reasons; however, during this period, we have discovered twenty-five cervical carcinomas in patients who have undergone cervical biopsy or an operation for some reason despite a negative smear. In some instances, the significant cells in these smears have been overlooked, whereas the smears in other instances did not contain significant cells. In the latter cases, poor sampling of the junctional zone, drying of the smears prior to fixation, or the presence of excessive amounts of blood, pus, or mucus would appear to explain the failure of smears. Between 1200 and 1500 cervical biopsies and 800 to 900 hysterectomies for various unrelated conditions are done each year at the clinic on patients who have had negative smears. These elective procedures tend to act as a limited check on our negative results.

The optimal period for obtaining repeat cervical smears cannot be stated categorically, although we arbitrarily have recommended a one-year interval between negative smears. During a six-year period, 17,760 women have had one repeat smear examined in our laboratory. In this group, thirty-nine preclinical carcinomas have been found, thus establishing a detection rate of 2.1 per 1000 women rescreened, a rate substantially below that in the initial screening smears. This reduced rate in repeat smears apparently indicates that the epithelial changes being detected are significant, for if these changes were unimportant the detection rate should be similar in both groups.

During the six-year period, 209 falsely suspicious smears were observed and investigated. Study of the biopsy material in these patients showed that 68 per cent of them exhibited some degree of basal cell hyperplasia or dysplasia of the cervical epithelium. Because of the frequent association of dysplasia or epithelial atypy with *in situ* squamous cell carcinoma at the junctional zone, we believe that one is duty bound to request a biopsy when only dysplastic changes are suggested from the cells found in the cervical smear.

From past experience, it has been learned that quadrant biopsy of the junctional zone of the cervix will yield the source of the cells found in the smear in approximately 85 per cent of cases. In more recent years, the pathologists at the clinic have prevailed on the surgeons to perform cold-knife conizing biopsy in order that we may study more thoroughly the junctional zone and at the same time render an opinion on the fresh frozen tissue as to whether carcinoma *in situ* is present, whether there is infiltration of the underlying stroma, or whether the cells found in the smear represent dysplastic changes that do not substantiate the diagnosis of carcinoma. In our opinion, conizing biopsy solves all three of the foregoing problems with a degree of finality that cannot be achieved with punch biopsy.

In selected cases, cutting out a cervical cone is used as a therapeutic as well as a diagnostic tool.

*Use of 95 per cent ethanol has proved to be satisfactory in our experience.

In general, however, treatment for *in situ* carcinoma of the cervix has been vaginal hysterectomy after cold-knife conization and frozen-section diagnosis. If one elects to use punch biopsy, it is imperative that cautery not be used and that hemostasis be obtained by the use of gelfoam and a vaginal pack until such time as the tissue diagnosis has been established. Our past experience has led us to believe that many unsolved instances of atypical or positive cells in the cervical smears have been the direct result of unsatisfactory punch-biopsy material and the injudicious use of the cautery at the time of biopsy.

A number of investigators recently have reported on use of cervical smears as a means of detecting invasive cervical carcinoma as opposed to *in situ* carcinoma. The presence of clinically detectable carcinoma of the cervix usually can be suspected in smears by certain nonspecific findings; however, we believe that these findings are far too variable and speculative to replace tissue diagnosis. In fact, information derived from such a method may be dangerous in that it may mislead the clinician and result in mismanagement of a patient.

Endometrium

The cytodetection of endometrial carcinoma has not been as satisfactory as has that of lesions of the uterine cervix. The detection rate in the hands of many investigators has averaged a little more than 50 per cent, which reflects the difficulty in consistently obtaining representative cytologic material from the endometrium in the vaginal pool. Aspiration of the endocervical canal and endometrial cavity offers the most satisfactory solution to this problem. However, both of these methods are cumbersome and time-consuming. In our experience, aspiration of the endocervical canal has not been rewarding. Many screening programs utilize the vaginal pool in addition to cervical scrapings for cytologic study in the hope of detecting early endometrial carcinoma. In our opinion, the chances of finding an early, completely asymptomatic endometrial carcinoma are so remote that we have preferred to concentrate our efforts on the discovery of preclinical carcinoma of the cervix.

Ullery and associates[5] reported a comparative study on 5260 women in whom cervical scrapings and smears from the vaginal pool were made at the same time in an effort to evaluate the comparative error. In this group, eleven carcinomas of the cervix were missed by use of the vaginal-pool smear.

Smears made after endometrial aspiration have been of value in the hands of some gynecologic surgeons who do not elect to subject their patients to preliminary curettage prior to abdominal operations. In a group of 901 patients with abnormal uterine bleeding, Hecht[6] found an incidence of endometrial carcinoma of 6 per cent; 58 per cent of these patients had positive vaginal-pool smears and 92 per cent had positive endometrial-aspiration smears. Four falsely negative results and five falsely positive results were encountered in the aspiration smears. In our opinion, abnormal uterine bleeding is best investigated by curettage and histologic study of the removed tissue.

The diagnosis of intra-abdominal carcinoma by use of vaginal smears occasionally is reported. We have found malignant cells from ovarian carcinoma and gastric carcinoma in smears and have recognized them as being from adenocarcinomas. Such cases are only of incidental interest and we attach little practical value to these findings in that a history and careful physical examination always have revealed findings of abdominal carcinoma.

Respiratory Tract

The diagnosis of bronchogenic carcinoma by cytologic examination of sputum or bronchial secretions has proved to be a valuable adjunct to diagnosis in persons suspected of harboring a pulmonary neoplasm.

At the clinic, it is customary in these studies to collect morning sputum in 95 per cent ethanol. The patients are instructed to collect only sputum from a productive cough and to avoid nasopharyngeal secretions. Five smears are prepared from each specimen by technicians trained in the selection of material from sputum. Three specimens are examined on consecutive days before an adequate negative cytologic examination has been considered to have been done.

In a study of 588 cases of miscellaneous thoracic diseases by Woolner and McDonald,[7] 147 cases of proved or suspected bronchogenic carcinoma were found, and 100 (68 per cent) of these were detected by cytologic examination of sputum or bronchial secretions. In a group of ninety-three patients, positive tissue diagnosis by bronchoscopic examination was obtained in 41 per cent. Recently, Umiker[8] reported a 69 per cent incidence of

sputum that gave suspicious or positive results for malignant cells in such cases.

The highest incidence of positive results was found in cases in which lesions were in the main-stem bronchi or in the lower lobes. Use of bronchial washings increased the accuracy of the bronchoscopic examination in upper-lobe lesions from 22 to 38 per cent.

The problem of occult carcinoma of the bronchus recently has been reviewed by Woolner and associates,[9] who reported fifteen cases encountered at the clinic during a thirteen-year period. These lesions were considered occult because minimal or no tumor was visible on gross examination of the surgical specimens. All patients with invasion beyond the bronchial wall were excluded, and all patients exhibited an extensive *in situ* component. Cytologic diagnosis played a prominent part in eleven cases, thus bringing the patients to operation early and presumably in a curable stage. One of these patients had positive cytologic results for three years prior to the development of bronchoscopic and roentgenologic findings. Bronchoscopic biopsy gave positive results in 47 per cent of these fifteen cases. A number of the patients who have had some form of pulmonary resection for carcinoma have been reported to demonstrate an *in situ* carcinoma in the opposite lung or in the bronchial stump at some time after resection. Cytologic studies of sputum after pulmonary resection for carcinoma would appear to be of value as a follow-up procedure.

Pulmonary cytology is basically an accessory laboratory diagnostic tool and not a screening tool for asymptomatic persons. Selectivity usually is based on abnormal roentgenograms of the thorax or a history of repeated pneumonitis or cough. Some success has been achieved with the aid of aerosol techniques in producing sputum in asymptomatic persons or in those unable to produce sputum despite roentgenologic evidence of a lesion. The rate of falsely positive results in pulmonary cytology is approximately 1 per cent. The exfoliated epithelium from lungs containing infarcts, organizing pneumonia, asthma, or bronchiectasis may originate from atypical squamous metaplasia associated with these conditions, and, therefore, be responsible for falsely positive or suspicious cells in the smear. The location of a lesion in the lung is of prime importance in the exfoliation of malignant cells. Recently, Woolner[10] demonstrated that peripheral lesions exfoliate cells into bronchial secretions or sputum at something less than half the rate in those lesions found in the main-stem bronchi. Cytologic studies also have proved to give a fairly accurate interpretation of the histologic type of carcinoma that may be expected in the resected lesion.

Pleural and Ascitic Fluid

For more than fifty years, physicians have been utilizing cytologic study of effusions as a means of establishing a diagnosis of malignant disease.

The smear technique and the paraffin-block method of examination of centrifuged sediment from an effusion tend to complement one another, but both methods may lead to falsely negative and falsely positive results. My associates and I[11,12] recently analyzed critically the data obtained from a battery of tests made on ascitic fluid from 132 patients in an attempt to obtain more reliable diagnostic information from the fluid. This group included sixty-nine patients with proved malignant tumors, forty-six with cirrhosis, nine with congestive heart failure and eight with miscellaneous conditions. A total of thirty-six (52 per cent) of the fluids caused by proved malignant tumors contained malignant cells. Two of the patients with cirrhosis were falsely judged to be shedding malignant cells in the ascitic fluid. These two observations serve to point out that extreme care must be exercised in evaluating cytologic studies of effusions. Leuallen and Carr[13] studied pleural fluids from 426 patients. They were able to detect malignant cells in 59 per cent of the patients with effusion and bronchogenic carcinoma, and in 54 per cent of the patients with carcinoma of the breast with effusion. Only 13 per cent of the fluids associated with malignant lymphoma or leukemia and effusion contained malignant cells. Half of the cases in which more than one specimen of fluid was examined cytologically revealed malignant cells in only one of the specimens.

When examining pleural or abdominal fluid for malignant cells, one must remember that the formation of fluid may not be caused by serosal irritation from malignant seeding but from lymphatic blockage or a nonspecific inflammatory process. Thus, the interpretation of cells in effusions is subject to considerable error.

Evaluation of the various metaplastic changes in mesothelial cells probably offers one of the greatest challenges in cytology. Tuberculosis, cirrhosis, and

nonspecific types of inflammation are among the lesions that most frequently are interpreted as malignant in origin. It is our practice to be conservative in rendering a definitive diagnosis of a malignant process in studies on effusions. A cytologic report of suspicious-appearing cells coupled with suggested clinical evidence may result in a completely erroneous diagnosis of malignancy, particularly in those cases in which the tissue diagnosis of a malignant tumor has not been established.

Genitourinary Tract

Carcinoma of the genitourinary tract may be diagnosed by study of cytologic smears of urinary sediment and prostatic fluid. The less well-differentiated carcinomas of the urinary bladder yield enough positive findings to be of limited value. In well-differentiated papillary tumors of the urinary bladder, cytologic studies have been disappointing in that the exfoliated cells closely resemble normal transitional vesical epithelium. The same situation holds true for tumors of the ureter and renal pelvis. In symptomatic patients, the well-established methods of diagnosis for lesions of the urinary tract should be utilized in an effort to establish a diagnosis, and cytology should be resorted to only in selected cases. Negative cytologic results in the presence of urinary-tract symptoms are of no diagnostic significance. The high rate of falsely positive results in lesions thought to be in the upper part of the urinary tract makes it compulsory that operations should not be undertaken without corroborative evidence of a lesion. In selected cases, cytologic studies in the hands of experienced observers may provide ancillary laboratory evidence of a malignant tumor when an indeterminate renal lesion is demonstrated by other diagnostic methods. The high incidence of falsely negative results renders the method valueless for the screening of asymptomatic patients. Feeney and co-workers[14] suggested that smears may be of limited value in following patients who have been treated for transitional cell carcinoma, since these neoplasms tend to be multicentric and recurrent. Atypical cells under these circumstances would be an indication for cystoscopic and pyelographic studies. Foot and associates[15] reported a detection rate of 61.7 per cent for carcinoma of the bladder, ureter and renal pelvis as part of a study of urinary sediments in 2829 patients.

Cytologic studies of prostatic fluid in the hands of some qualified and interested investigators have yielded encouraging results. There is a tendency for a high rate of unsatisfactory smears in that it is difficult to collect and prepare the material. Recently, Clarke and Bamford[16] reported on 543 smears of prostatic fluid from 442 patients. Falsely negative results were obtained in 54 per cent of their series of cases and falsely positive results in 0.5 per cent. These authors were of the opinion that in men fifty years of age or older, palpation of the gland offered the best means of diagnosis prior to operation. Adenomyosis, chronic prostatitis, fibrosis, and prostatic calculi yielded a high percentage of atypical cells in the smears. These atypical cells easily may lead an unsuspecting cytologist to report an excessively high number of falsely suspicious smears. In routine practice, the prostatic smear is of little practical value in the detection of preclinical carcinoma of the prostate gland. As in the case of the kidney, the prostate gland is not readily available for complete histologic study and, unless a nodule can be palpated, one has no choice in selecting material for biopsy in order to confirm or disprove the cytologic findings. It is doubtful if smears of urinary sediment offer the clinician much help in the diagnosis of malignant lesions of the urinary tract that can be demonstrated readily by the more conventional diagnostic methods.

Stomach

Gastric secretions have not been widely utilized as a means of detecting malignant tumors of the stomach. Reports in the literature indicate that the yield of significant cells in gastric smears has varied from 33 to 95 per cent.[17] Because of the apparent difficulty in the cytologic detection of proved gastric carcinoma, many cumbersome and elaborate methods have been devised by which one may increase the number of gastric epithelial cells or malignant cells in the aspirated secretion.

Under certain conditions, malignant cells doubtlessly may be demonstrated in smears of gastric secretions; however, it is questionable as to how much these findings contribute to the discovery of early curable carcinoma of the stomach. Very occasionally, a gastric lesion that otherwise would be treated as benign has been found to be malignant through the use of gastric cytology. Negative results must be considered of little significance in the face of a rather high and consistent rate of

falsely negative results. The very nature of gastric carcinoma tends to produce falsely negative results in that many lesions are scirrhous in nature, and ulceration with superficial necrosis is frequently a predominant feature. The unusual lesion with mucosal spread and a large free surface from which to exfoliate cells is the lesion par excellence for detection by cytologic means.

A number of reports have demonstrated an extremely high correlation of positive smears with histologically proved gastric carcinoma. However, it is not clear from these reports as to how many of the lesions were diagnosed as malignant or as being suspiciously malignant by roentgenologic studies. To put it another way, how many unsuspected carcinomas were revealed by cytologic studies in patients diagnosed as having some benign lesion or as having no pathologic changes after an adequate history, a thorough physical examination, and roentgenographic studies? We are endeavoring to answer these questions. To date, we have studied gastric washings from slightly more than 100 patients. Malignant cells were demonstrated in the gastric washings from one patient who otherwise would have been diagnosed as having functional vomiting. This patient had a hiatal hernia and bizarre abdominal complaints. The gastric roentgenogram did not reveal any abnormal mucosal changes. The surgical specimen revealed a superficial carcinoma approximately 5 cm. in circumference associated with distant metastasis.

In another patient in whom malignant cells were found in the gastric washings, a roentgenologic diagnosis of carcinoma had been made. At operation, the surgeon was undecided as to whether the palpable lesion was malignant or represented some benign condition. On the strength of the cytologic findings, radical subtotal gastric resection was done. It was the surgeon's opinion that if he had proceeded on the basis of his clinical impression of the gross lesion, he would have attempted a less radical procedure and would have had to resort to removing the node-bearing tissues and spleen after having received the frozen-section diagnosis of carcinoma. This would not have particularly jeopardized the success of the surgical procedure but would have added approximately one hour to the length of the operation.

While both of these cases are interesting and represent the value of gastric cytology, they are unusual and basically are not the type of case that we are trying to evaluate. At present, our goal is to aid the internist in the management of an ulcerating gastric lesion that may or may not be benign. Cain and associates[18] demonstrated in approximately 10 per cent of ulcerating gastric lesions that the clinician is unable to arrive at a firm conclusion as to whether the lesion is a benign peptic ulcer or a small ulcerating gastric carcinoma. In approximately half of these cases, microscopic examination of the edge of the ulcer is necessary before the diagnosis of benignancy or malignancy is established. Until falsely negative results can be eliminated with a high degree of certainty, it appears that one must continue to treat these indeterminate ulcerating gastric lesions as being potentially malignant and to advise immediate surgical intervention rather than watchful waiting.

Lower Part of Esophagus and Cardia

The cytologic technique may be of considerable aid in the diagnosis of lesions in the lower part of the esophagus and in the cardia of the stomach.[19,20] Smears from this location usually are made directly from the lesion at the time of esophageal dilation by the use of cotton swabs, or they may be made directly from the esophageal dilator. Such smears are of use in clinically suspected malignant tumors and are of value in increasing the accuracy of biopsy, because material for biopsy often is necrotic or small in amount. This procedure is definitely an ancillary method to biopsy, but it has proved to be valuable in selected cases. A high degree of accuracy may be expected from this method.

Colon

A few enthusiastic reports in the literature call attention to the utilization of cytologic studies for detection of carcinoma of the colon above the proctoscopic range. Raskin and co-workers[21] recently reported thirty-eight proved colonic carcinomas in which results of cytologic studies were positive in thirty-six instances, together with a negative cytologic report in 145 cases. In ten of these thirty-six cases, the initial barium enema failed to make the diagnosis of carcinoma. These authors stated that five of the patients were subjected to repeat roentgenologic examinations only after a positive cytologic report was made. The preparation of washings from the colon is a time-consuming procedure and, while it may be of some value in selected cases, it is doubtful if this method

of cancer detection ever will become widely accepted by either the patient or the cytologist.

Mammary Gland

Much disagreement exists among physicians as to the significance of a bloody or serous discharge from the nipple and as to the best method of treatment in such cases. This dilemma naturally fosters the cytologic approach as a method of establishing the nature of the discharge. One should keep in mind that discharge from the nipple in the absence of a mass rarely is caused by carcinoma. If a mass is present in the breast, one should not temporize by making smears of the discharge but should resort to biopsy and then base therapeutic measures on the tissue report. According to Haagensen and associates,[22] 1.3 per cent of carcinomas of the breast are associated with serous or bloody discharge from the nipple. Madalin and co-workers[23] were able to demonstrate one carcinoma in 100 breasts removed because of discharge from the nipple; in this instance, the lesion was extremely small and was discovered after the breast had been removed as a prophylactic simple mastectomy because of carcinoma in the opposite breast. A total of forty-four of the 100 breasts exhibited intraductal papillomas, with the lesions being multiple in six instances.

Papanicolaou and associates[24] reported their experience with the cytologic study of mammary secretions in 1066 patients. In a group of forty-five proved mammary carcinomas, 60 per cent of the smears were considered suspicious or positive for carcinoma. Examination of smears from 613 breasts in 438 asymptomatic women disclosed one case of unsuspected *in situ* mammary carcinoma. Cellular clumps in cases of intraductal papilloma are said to be characteristic. Negative cytologic findings associated with a mass in the breast are unreliable and should not be considered of any value.

Positive findings may confirm a clinical impression, but they do not replace tissue diagnosis. A negative report, in the absence of a palpable lesion, particularly when associated with the cytologic picture of a papilloma, may be considered as significant. This concept is strengthened when one considers the statistical data pointing out the uncommon occurrence of discharge from the nipple associated with carcinoma. If smears of the secretion are to be made, one must remember that fixation of the wet smears is imperative in order to prevent distortion of the cells through drying. It is questionable if smears of mammary secretions will be of much help to the practicing physician as a means of detecting unsuspected carcinoma of the breast, and they actually may give a sense of false security.

Cerebrospinal Fluid

Smears of the sediment from cerebrospinal fluid occasionally are studied in an attempt to identify cellular types that cannot be recognized by the usual counting-chamber technique. Such studies also may be made in patients with bizarre neurologic findings and pleocytosis.

In our experience, satisfactory smears may be prepared by fixing the centrifuged sediment on frosted slides in 95 per cent ethanol and staining by the routine methods with hematoxylin and eosin. The total cell count and the proportions of identified cells are noted so as to give a rough estimation concerning the number and type of cells that should be found in the stained sediment. McCormack and associates[25] expressed a preference for the wet-smear technique using toluidine blue.

Smears of cerebrospinal fluid most often are useful in demonstrating carcinomatosis of the meninges, but cells from gliomas may be demonstrated on rare occasions.

The usually deep-seated location of malignant lesions in the brain accounts for the extremely rare phenomenon of shedding of malignant cells into the cerebrospinal fluid. In our experience, medulloblastomas are the most common gliomas to seed on the meninges, but seeding of astrocytomas and pinealomas has been reported. The relationship of the usual medulloblastoma to the fourth ventricle, in addition to its highly malignant nature, probably accounts for its more unorthodox behavior.

Malignant lymphomas and leukemia rarely may exfoliate cells into the cerebrospinal fluid. In metastatic lesions, particularly with a known primary source, the presence of malignant cells in the cerebrospinal fluid obviates craniotomy in the light of a hopeless situation.

Summary and Conclusions

Under certain optimal conditions, it is possible to demonstrate malignant cells in body fluids and secretions. It is also evident that cytologic studies in many instances are an unnecessary refinement

that may be added to well-established diagnostic methods. In selected cases, cytology has proved to be a valuable adjunct in arriving at a correct diagnosis that otherwise might have been overlooked. The rather high rate of falsely negative results obtained in most situations, except in those organs (such as the cervix) that can be readily seen, is a serious defect in the method.

The high degree of accuracy in suspected pulmonary neoplasms so situated as to exfoliate malignant cells has been of considerable value to surgeons in the operative treatment of carcinoma of the lung. A rate of falsely negative results of nearly 60 per cent in peripherally located carcinomas makes it necessary that most "coin lesions" be surgically removed for diagnosis.

The use of cytologic techniques as a screening method for the detection of preclinical carcinoma is applied most successfully to the uterine cervix. From the standpoint of screening large numbers of asymptomatic patients for malignant tumors, the uterine cervix is unique and offers the most promising field in the early detection of cancer for the practicing physician.

Descensus Uteri and Prolapse of the Vaginal Vault and Enterocele

Clinical and Surgical Considerations

Dr. Kempers is Fellow in Obstetrics and Gynecology, Mayo Foundation; Dr. Smith is in Section of Obstetrics and Gynecology, and Dr. Pratt is in Section of Surgery, Mayo Clinic, Rochester, Minnesota.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

REGINALD A. SMITH, M.D.
JOSEPH H. PRATT, M.D.

Rochester, Minnesota

Uterine prolapse undoubtedly has plagued womankind ever since she acquired an erect posture and a soul. This article touches on the conservative management of prolapse, but it currently emphasizes that surgical correction is needed for cure. Use of vaginal hysterectomy is the technique of choice for repair.

UTERINE prolapse, or descensus uteri, may be likened to a hernia since the uterus and adjoining structures protrude through the vagina. It occurs with different degrees of severity. In first-degree prolapse, the uterus lies below its normal level but the cervix does not protrude from the vulva; second-degree prolapse is characterized by protrusion of the cervix at the vulva; in third-degree prolapse, or procidentia uteri, the entire uterus is extruded from the vagina and the entire vagina may be inverted.

Associated with prolapse of the uterus is some degree of involvement of the vaginal walls, bladder, urethra and rectum. Rectocele is partial herniation of the rectal wall into the vagina caused by stretching or laceration of the rectovaginal septum and separation of the levator ani muscles. Cystocele is partial herniation of the base of the bladder into the anterior part of the vagina caused by stretching of the vesicovaginal septum and relaxation of the pubocervical fascia and the cardinal-ligament system. Enterocele is an outpouching of the cul-de-sac of Douglas immediately behind the cervix between the uterosacral ligaments.

Etiologic Factors

The great majority of prolapses are preceded by lacerations during childbirth. Prolapse is encountered most frequently in older persons. Postmenopausally, loss of elastic fibers and atrophy of the vaginal mucosa often result in an increase in subjective complaints. It is during this time that a sudden increase in symptoms causes many patients with pelvic relaxation to seek aid.

Prolapse of the uterus occasionally is seen in women who never have borne children; in these patients, the cause may be congenital weakness of supporting tissues or may be on a neurogenic basis.

Repair of pelvic relaxation, which includes various degrees of descensus uteri, cystocele or rectocele, is the commonest indication for vaginal hysterectomy at the Mayo Clinic.[1] This indication was present in 254 (61 per cent) of the 415 patients who underwent vaginal hysterectomy here in 1955. Many patients who had severe uterine descensus were postmenopausal (Table I). Ninety of these 254 patients were sixty years of age or

TABLE I. AGE DISTRIBUTION BY INDICATIONS IN 415 CONSECUTIVE VAGINAL HYSTERECTOMIES AT THE MAYO CLINIC IN 1955*

Age, Years	Indications				
	Repair	Bleeding	Carcinoma in Situ	Fibroids	Miscellaneous

Total	254	75	65	7	14

*From data presented in an article by Kempers and associates.[1]

older, and the oldest was more than eighty; this group included only twelve nulliparous patients beyond the menopause who had sufficient relaxation to warrant repair.

Signs and Symptoms

The patient with uterine descensus usually complains of a sensation of "falling out" of the vagina. She also may complain of backache, a dragging sensation in the pelvis, or a feeling of "sitting on a ball."[2] Vaginal bleeding, when present, is usually slight in amount and generally is caused by superficial ulcerations of the vaginal mucosa or cervix. Since most of these women have other associated features of pelvic relaxation, there also may be complaints referable to vesical descent, such as stress incontinence, or perineal relaxation, constipation, hemorrhoids and other rectal discomfort. Occasionally, patients who have severe cystocele may be perfectly continent, only to become incontinent after repair unless the repair has been performed properly and has included the tissues under the urethra. Jeffcoate[3] recently re-emphasized the importance of making the diagnosis of rectocele before the patient is anesthetized. Patients frequently have adequate support; however, the tissue relaxes when they are placed under anesthesia, and the tissues may become stretched when a weighted speculum is suspended from the vagina, producing a false impression of some degree of rectocele.

It is possible on occasions to mistake for simple prolapse the condition of hypertrophy and elongation of the cervix, which may occur with little or no pelvic relaxation. In such a situation, the cervix may be seen at or beyond the introitus, but examination reveals that the fundus is still high and well supported and possibly enlarged to the extent that vaginal hysterectomy would be difficult.

Pathologic Aspects

Other associated pathologic conditions may be present in addition to prolapse of the uterus, cystocele, rectocele and enterocele. Commonly, large amounts of residual urine contribute to the development of cystitis. When the cystocele is pronounced, angulation of the ureters may be present. However, subsequent hydroureter, hydronephrosis and pyelitis are rather rare.

Erosion, infection and the formation of decubitus ulcers on the cervix and vaginal mucosa are not unusual as the result of friction against the patient's thighs, clothing or protective napkins. A skinlike thickening of the vaginal mucosa that resembles leukoplakia may be produced by the drying action of air. While carcinoma may develop in these cervices, it has long been thought that the prolapsed cervix enjoys relative immunity to malignant disease,[4] an immunity that may be related to dryness of the tissue and the freedom from irritation by vaginal secretions. However, Taylor[5] found carcinoma of the cervix in prolapsed uteri on numerous occasions and considered that the patient with prolapse has no immunity to malignant changes in the cervix. This opinion is upheld in a recent report by Rocker,[6] who noted an 18 per cent incidence of malignant changes in procidentia and found carcinomatous changes in approximately 25 per cent of patients more than sixty years of age, in the majority of whom the procidentia had been present for more than ten years. At the clinic, except for an occasional in situ carcinoma, the combination of malignant tumors of the cervix and prolapse is extremely rare.

Anatomic Considerations

The following, with slight modifications and additions, is a summary of the supporting structures of the uterus and their respective functions as outlined by TeLinde.[7] These must be well understood in order best to utilize these structures in the surgical cure of prolapse.

Round Ligaments.—These ligaments draw the uterus forward and resist its backward displacement. One of the prime functions of these ligaments during pregnancy, when they are hypertrophied, is to hold the uterus in an optimal position during labor to allow the forces of labor to be directed through the pelvic axis. With relaxation of these ligaments and retrodisplacement, the axis of the uterus may be in the same direction as that of the vagina, and intra-abdominal pressure may force the uterus into the vagina in a pistonlike manner. However, if the other supporting structures are intact, the retrodisplaced uterus does not descend, although additional strain is placed on these other supporting structures.

Uterosacral Ligaments.—These ligaments are part of the endopelvic fascia and are continuous with the system of cardinal ligaments. They extend from the cervix posteriorly and aid in holding the cervix up and back. The cervix is displaced forward and downward when these ligaments are stretched as a result of childbearing, or if they are

congenitally long. This also causes retrodisplacement of the uterus and, again, the axis of the uterus is in the same direction as that of the vagina, facilitating intra-abdominal pressure to force the uterus into the vagina.

Cardinal Ligaments.—These ligaments, also called Mackenrodt's ligaments, are situated at the bases of the broad ligaments and are also continuous with the endopelvic fascia. They fan out laterally toward the sides of the pelvis from their lateral attachment on the cervix. These ligaments also may be congenitally relaxed, occasionally being considerably relaxed in nulliparous women who never have done strenuous work.

Fascial Sheath.—Encasing the vagina and making it a semirigid structure is a sheath of fascia that is continuous with the cardinal-ligament system. Anteriorly, it usually is described as the pubovesicocervical fascia and posteriorly as the rectovaginal fascia. Stretching or laceration of these fascial structures may result in rectocele and cystocele.

Muscular Floor of Pelvis.—Forming the floor on which the uterus and its supporting structures rest are the levator ani muscles. Descent of the uterus is facilitated when these pubococcygeal fibers become stretched or lacerated.

Mengert,[8] in 1936, investigated and described the relative significance of the various ligaments. He attached a 1-kg. weight to the cervix of each of eight cadavers and studied the effect of cutting paired uterine supporting structures. He found that the round, ovarian and infundibulopelvic ligaments, and the upper third of the broad ligaments, as well as the pubocervical fascia, had a negligible role in the support of the uterus. He noted also that the pelvic floor did not contribute much support since, after all other structures had been cut, the pelvic floor did not prevent prolapse. However, section of the lower two thirds of the broad ligament caused a uterine descent of 3.6 cm. and section of the upper third of the paravaginal tissue alone caused a descent of 6.9 cm. Severance of both of these structures allowed a descent of 10.5 cm. The uterosacral ligaments add a small amount of support because they are related so closely to the paracervical tissue. Thus, the paravaginal fascia of the upper third of the vagina and that of the cervix apparently are the most important structures in preventing descensus uteri.

Conservative Management of Uterine Prolapse

It is usually possible to support a prolapsed uterus with a properly fitted pessary, but the pessary should be used only with the understanding that it is a temporary support. We agree with Wharton,[9] who stated that it should rarely, if ever, be used in younger women for more than six months; in older women, its continued use may be necessary but is an admission of lost opportunity or inoperability. Occasionally, surgical correction may be contraindicated because of the patient's general physical condition, cardiac disease, diabetes, or hypertension, or because of far-advanced physiologic age. Rarely, one may see a woman with such pronounced relaxation of the pelvic diaphragm and perineum that a pessary cannot be worn. Once a pessary has been fitted, the patient must be instructed to remove and cleanse it frequently and to return for periodic medical inspection of the vaginal walls. Any evidence suggestive of inflammation or ulceration of the mucosa warrants leaving the instrument out of the vagina for a time. Certain types of pessaries may be removed with ease by the patient at bedtime or at times of minimal activity. Daily cleansing douches are necessary.

A great variety of pessaries are available, and the selection of the proper one may vary with individual circumstances. Taylor[5] advocated a soft, round, rubber "doughnut" pessary if the descensus is not excessive. This instrument supports the uterus by spreading the walls of the vagina in all directions and thus tensing the vaginal supports. Another widely used pessary is the Smith-Hodge type, which fits behind the pubis and exerts countertraction on the uterosacral ligaments and vagina. The fornix is pushed upward and backward, drawing the cervix in the same direction and consequently causing the fundus to be antiflexed. This pessary is recommended particularly for retroversion of the uterus and not for severe descensus. The round-ball pessary, the mushroom pessary, and the bee-cell pessary are all available for individual circumstances.

Occasionally, it is practical, particularly in the immediate postpartum period, to advise use of the perineometer, devised by Kegel,[10] for patients with mild laxity of the perineal muscles as well as mild urinary stress incontinence. Use of the perineometer at home for twenty minutes three times a day for several weeks frequently restores tone to the

perivaginal and periurethral muscles and restores function to the vaginal and urethral sphincters.

Another approach to conservative treatment has been reported by Anderson.[11] Using oral and parenteral administration of conjugated estrogens in four postmenopausal women with procidentia who either had refused operations or were poor surgical risks, he found that the procidentia disappeared after a few weeks of treatment. He suggested that perhaps the estrogens had restored the tone of the cardinal ligaments. Further confirmation must be awaited.

Surgical Measures

The surgical correction of uterine descensus is necessary for cure. Any progression in the amount of descensus or relaxation between periodic pelvic examinations indicates need for surgical repair since moderate relaxation is easier to repair than are the more severe forms, and a more satisfactory and functional vagina can be obtained. Age itself is not a contraindication; although the risk of any surgical procedure increases with age, the risk of vaginal hysterectomy is minimal, being approximately 0.1 per cent at the clinic.[1]

The more widely accepted procedures for surgical repair of descensus uteri are listed below. Satisfactory repair of stretched and scarred uterine supporting structures should be accomplished through the vagina. The abdominal procedures, such as uterine suspension and ventral fixation, should not be done for correction of uterine descensus unless repair of the vaginal walls is carried out at the same time.

Vaginal Hysterectomy.—Removal of the uterus through the vagina, with repair of the anterior and posterior vaginal walls, is the method favored in most American clinics. The principal steps in this procedure have been well described previously by Counseller[12] and by Pratt.[13] During vaginal hysterectomy and repair, an enterocele may be missed if the surgeon is not fully cognizant of the problem. Its repair or prevention is accomplished by obliterating or excising the redundant cul-de-sac of Douglas and then excising a corresponding wedge of mucosa from the posterior fornix.

Spalding-Richardson Operation.—This technique is recommended enthusiastically by TeLinde[7] as the operation of choice for many patients with prolapse. Advocates of this procedure are of the opinion that better support for the vaginal apex is obtained than with simple vaginal hysterectomy. The operation is basically subtotal hysterectomy and amputation of the lower part of the cervix. The middle portion of the cervix is preserved and utilized as a base for reattachment of the ligaments. This is followed by repair of the cystocele and colpoperineorrhaphy.

Manchester-Fothergill Operation.—This procedure[14] is used widely in England and Canada. The operation is especially applicable in less advanced degrees of descensus uteri because the parametrial tissues must be capable of aiding uterine support. Although original descriptions of this procedure suggested cervical amputation, this need not be accomplished if the patient still is interested in childbearing. In this procedure, the cardinal ligaments are reattached to the front of the uterus, holding the uterus upward and backward.

Colpocleisis.—Surgical closure of the vaginal canal[14] has a limited field of application and is contraindicated if the patient wishes to have sexual intercourse even occasionally. Therefore, use of this operation should be confined to the surgical treatment of elderly widows and patients who are considered to be poor surgical risks for any of the other procedures. The operation entails obliteration of the vaginal canal by approximation of the denuded vaginal walls with sutures. The most widely used of the colpocleisis techniques today is the Le Fort operation.

Watkins' Interposition Operation.—This is one of the oldest procedures for procidentia.[7] After cervical amputation, the uterine fundus is brought through an opening in the peritoneum of the anterior cul-de-sac, and the peritoneum is then sutured to the posterior wall of the lower uterine segment. The cornua are sutured to the subpubic arch, and the anterior surface of the uterus is covered by vaginal mucosa.

Prolapse of the Vaginal Vault After Total Removal of Uterus

According to Taylor,[5] the general experience is that 85 per cent of patients have satisfactory results after surgical repair of uterine prolapse, regardless of whether vaginal hysterectomy, the Spalding-Richardson method or the Manchester-Fothergill technique is used. However, only some of the remaining 15 per cent need further surgical treatment. The unsatisfactory results may occur, as in-

dicated previously, because a potential enterocele is not recognized and repaired at the time of operation for prolapse. Hematomas, pelvic infections and abscesses also may prevent proper healing of the repaired structures and result in weakened supports. The probability of successful repair of the prolapse is greatly increased if, associated with this procedure, good repair of the cystocele and rectocele is accomplished.

Many operations have been suggested for correction of the prolapsed vault or enterocele or both.[14] These have included fastening the apex of the vagina to the uterosacral ligaments and fascia over the fascia of the sacrum, or suturing the prolapsed vagina to the anterior abdominal wall. A number of fascial-sling operations have been described, and the Le Fort operation has been utilized.

The procedure used at the clinic is much like that for repair of the prolapsed uterus. An attempt is made vaginally to locate the cardinal and uterosacral ligaments; these are anchored together at either side of the apex of the vault, and any indicated repair of cystocele or rectocele then is carried out. Symmonds and Pratt[15] recently reviewed the examples of posthysterectomy prolapse seen at the clinic from 1945 through 1949; of sixty-nine such cases, thirty-nine followed hysterectomy performed elsewhere, the previous operation being either abdominal or vaginal hysterectomy. The remaining 30 instances of prolapse of the vault followed operations performed at the clinic, including twenty-one vaginal and nine total abdominal hysterectomies. Of the twenty-one cases of prolapse after vaginal hysterectomy, thirteen were examples of the technique of vaginal hysterectomy in which the paired ligaments are sutured to each other across the apex of the vault and then pulled forward beneath the bladder, which leaves a gap behind and between the uterosacral ligaments. With use of the current technique, it is thought that postoperative enteroceles will be seen less frequently than in the past.

The repair of recurrent prolapse of the vault with subsequent provision of a functional vagina is indeed a difficult problem. Symmonds and Pratt noted that 87 per cent of the patients undergoing repair of a prolapsed vault had satisfactory results. Although the approach may be made either abdominally or vaginally, we prefer the latter route, since repair requires some reconstruction of the vaginal walls.

Summary

Uterine prolapse may be of varying degrees of severity, ranging from displacement just below the normal level to extrusion of the entire uterus from the vagina. Generally, there is associated involvement of the vaginal walls in the form of rectocele, cystocele or enterocele.

The commonest cause of prolapse is injuries during childbirth, but occasionally it is seen in nulliparous women. Symptoms include "falling out" of the vagina, backache, a dragging sensation in the pelvis, or a feeling of "sitting on a ball." Other common symptoms are stress incontinence, constipation and hemorrhoids.

Most authorities agree that carcinoma is extremely rare in the prolapsed cervix.

Temporary support derived from pessaries may be indicated in some cases. However, surgical correction is required for cure. Vaginal hysterectomy, with repair of the vaginal walls, is the most widely used surgical technique. If postoperative prolapse of the vaginal vault occurs, it may be repaired by using a vaginal approach similar to that utilized in vaginal hysterectomy and repair.

Transventricular Approach to Mitral Valvotomy

W. ROBERT SCHMIDT, M.D.
JOSEPH J. GARAMELLA, M.D.
NATHAN KENNETH JENSEN, M.D.
Minneapolis, Minnesota

MOST SURGEONS have found the blind auricular approach satisfactory for the correction of the type of valvular stenosis that splits easily and widely with application of digital pressure in the direction of the commissures. However, where simple "finger fracture" fails and it becomes necessary to use instrumentation to divide the commissures, adequate mobilization of the valve is frequently not obtained. As experienced a surgeon as Bailey reported opening only one commissure in more than two-thirds of his first 1,000 patients producing an aperture estimated at only 25 per cent of the normal area. Dissatisfied with this approach, Bailey[1] popularized the right thoractomy, left atrial, approach which has proved to be satisfactory in his hands. However, using this latter approach, we have found it difficult to divide accurately the anterolateral commissure.

Long-term follow-up of patients subjected to mitral commissurotomy by the standard left atrial approach, shows that sustained improvement occurs in 66 per cent of cases, Bailey;[2] 66 per cent, Ellis;[3] 63 per cent, Turner;[4] 65 per cent, Baker.[5] While this is a considerable improvement over results treated by medical means alone, the failure of approximately one out of three operated patients to exhibit either lack of improvement, or lack of sustained improvement, accentuates the need for better surgical correction of the valve defect.

Restudy of the poor result group, using combined right and left heart catheterization techniques, shows in most instances that the deteriora-

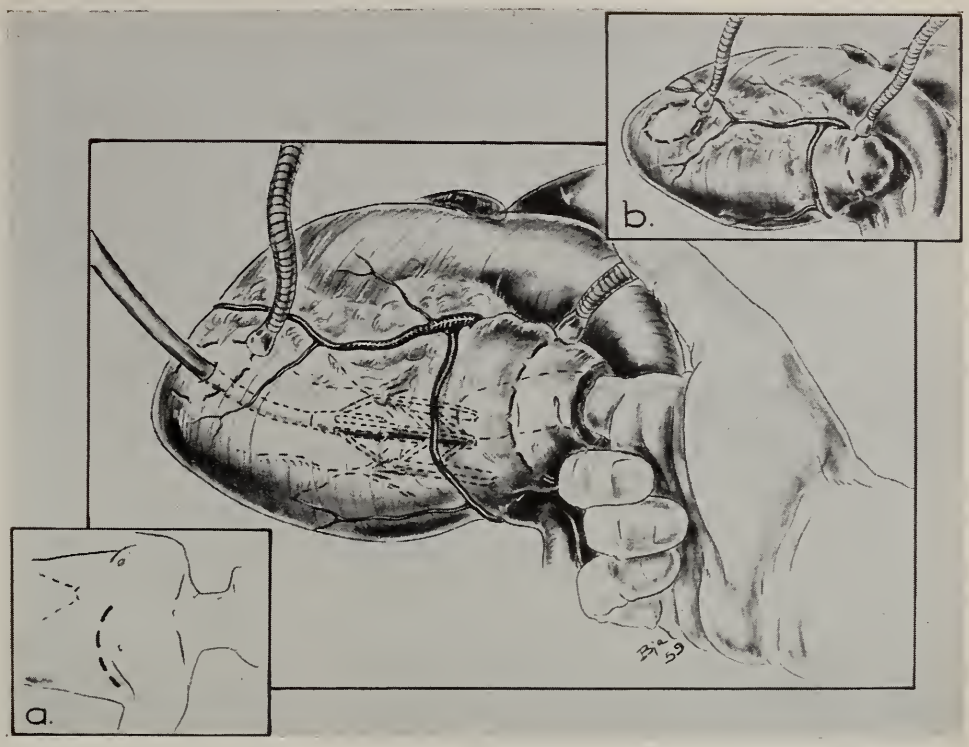

Fig. 1. *(a)* Chest is entered through the left fifth interspace. *(b)* Purse strings placed around the apex of the left ventricle, and at the base of the left auricular appendage. The *center* illustration shows the operator's finger inserted in the left atrium for inspection of the valve and direction of the dilator to its proper position in the mitral orifice. The dilator has been inserted through the apex of the left ventricle and has been opened to begin dilatation of the mitral valve.—(Reproduced through the courtesy of Dr. Denton A. Cooley, and the C. V. Mosby Company, from *Surgery,* 46:415, Aug., 1959).

tion of the patient is due to an inadequate valve orifice. We feel that the term "restenosis"[6] is a useful term to apply to those operated patients who have shown a striking initial improvement followed later by deterioration, provided the deterioration can be ascribed to an inadequate valve orifice. In reviewing the original operative reports on our patients who have developed recurrent symptoms of mitral heart disease due to restenosis, we note only an occasional case in which the valve split widely in both commissures. Recurrences[7] are obviously much more frequent in cases where valvotomy required incision by instrumentation and where mobilization of the valve was incomplete.

During the past year, Conklin[8] and also Cooley,[9] in this country, and Logan and Turner,[10] and Crum[11] in England, reported results of mitral commissurotomy accomplished by a two-bladed expanding dilator introduced by the transventricular route. Because of our dissatisfaction with the results obtained by transatrial valvotomy, we have

used the transventricular procedure in our last sixteen cases. The method appears to have considerable advantages over previous types of blind valvotomy.

Technique

In the transventricular approach to mitral valvotomy, a two-bladed dilator is inserted through a stab wound in the apex of the left ventricle and directed into the mitral valve from below. The position is checked by a finger inserted through the left atrium (Fig. 1). Blood loss (controlled by purse string apical and ventricular sutures) has been minimal. We have had no difficulty in avoiding the chordae tendineae and in placing the blades in proper position.

After the dilator is placed in proper position in the stenotic mitral orifice, and its position checked by means of the finger introduced through the left atrium, pressure is applied to the dilator until the valve splits. The dilator is then removed and the extent of the split checked. Usually, one can open the dilator to maximum size (3.5 cm.). After withdrawal of the dilator, the incision in the myocardium is closed with three or four silk sutures and the purse-string suture removed. The atrial incision can be closed in the usual manner, and the atrial appendage amputated. Occasionally, where the fish-mouth type of orifice of mitral stenosis is eccentrically placed with one commissure very short, and one very long, only the long commissure will split. In this situation, we have found it helpful to introduce the finger from the atrial side to the area of the commissure that has split and then reinsert the dilator from below and with the finger in place so as to protect the side that has already been split, all of the force of the dilator will be exerted against the unsplit commissure.

Results

We have been pleasantly surprised by the extent of the split obtained with the dilator. Usually both commissures split widely. In addition, the degree of mobilization of the septal cusp has been much greater than we have routinely obtained by other methods. The subvalvular stenotic area splits along with the commissural stenosis, something we were never able regularly to accomplish using the atrial approach. Bailey, as well as Logan and Turner, emphasize the advantages of splitting the commissure not merely to the atrial ventricular ring but continuing the split in a curved fashion along the free margin of the septal cusp so as to more adequately mobilize the latter valve cusp. This degree of mobilization can rarely be obtained by digital fracture. Most surgeons would hesitate to attempt this degree of mobilization with cutting instruments applied transatrially for fear of producing severe traumatic regurgitation. However, using the two-bladed dilator, applied through the ventricle, one can usually accomplish this degree of mobilization without undue risk. Initially, we were concerned about the likelihood of producing a traumatic regurgitation with what appeared to be a rather crude instrument. In thirty-eight cases, Conklin reports no increase in the operative risk (3.8 per cent) with less likelihood of producing or increasing valvular insufficiency. Cooley, eighteen cases, reports insufficiency as a complication in one case only, and that was treated successfully by subsequent open valvuloplasty. Turner and Logan, in 438 cases, using transventricular dilatation, report six fatalities (1.4 per cent) from traumatic incompetence, as compared to four deaths (1 per cent) from traumatic incompetence in 388 operations using the atrial approach. In sixteen cases of our own, significant valvular incompetence occurred as a complication of the operative procedure in one instance as will be described below.

Our own experience in mitral valvotomy done by the transventricular method includes sixteen cases operated on between May 1959, and April 1960. The ages range from thirty-one to fifty-seven. Six of the sixteen patients had had a previous valvotomy. One patient had had two previous valvotomies with relief of symptoms for four years after each procedure. In thirteen of the sixteen patients, both commissures were opened. In three patients the fish-mouth orifice was placed very eccentrically and in these three only the posterior commissure was opened. Postoperatively, the mitral orifice was considered to be quite adequate in all instances, and the degree of mobilization of the aortic valve cusp in all instances was accomplished to a much greater degree than we have been able to manage with the transatrial operation. There were two major complications, both occurring in the same patient (C.S.). This patient developed signs of massive cerebral embolism which occurred twenty-four hours after

TABLE I. RECORD OF SIXTEEN CASES

Case	Sex	Age	Date	First Operation	Repeat Operation	Both Commissures Opened	One Commissure Opened	Size of Aperture (Estimation)	Significant Incompensation
1. M.G.	F	50	1-20-60		x	x			0
2. S.B.	F	32	4- 5-60	x		x		3½ cm.	Grade 1
3. S.L.	F	28	3- 4-60		x	x		3 cm.	Grade 1
4. M.S.	F	45	3-15-60		x	x		3 cm.	0
5. L.H.	F	35	3- 2-60	x		x		Not recorded	Grade 1 pre 0 after split
6. M.P.	F	45	2-23-60	x			x (posterior)	Adequate	0
7. V.A.	M	40	2-19-60		3rd oper.	x		2½ fingers	Grade I-II 0 after split
8. B.M.	F	31	11-18-59	x		x		Not recorded	0
9. W.S.	M	57	9- 3-59	x		x		2½-3 fingers	1+ regurg.
10. N.W.	F	54	7-15-59		x		x (posterior)	3 cm. or better	1+ regurg.
11. J.A.	M	36	10-26-59	x		x		3 cm. or better	0
12. I.M.	F	37	11- 4-59		x		x (posterior)	3½ cm.	0
13. D.H.	F	32	7-31-59	x		x		2+ fingers	0
14. L.D.	M	44	6- 8-59	x		x		Not recorded	0
15. M.A.	F	34	5-21-59	x		x		3 fingers	0
16. C.S.	F	45	3-23-60		x	x		2½ cm.	2+ regurg.

surgery. The patient had an extensively calcified valve which had been split in the anterior commissure at a previous operation some five years before. At the time of her second operation, the mitral area had degenerated to essentially a tunnel of calcified and fibrotic tissue. The valve cusps were unrecognizable, as such. This patient not only developed an embolus but had a significant regurgitation following dilatation of the valve. The extent of the regurgitation was reduced by insertion of an Ivalon pad placed between the pericardium and the wall of the atrium at the atrial ventricular ring. Catheterization preoperatively revealed a pulmonary artery pressure of 100 in this patient. Postoperatively, her cardiac status is satisfactory. However, she has residual paralysis in the right arm and right leg and is aphasic.

The remaining fifteen patients have had no major complications and they are all strikingly improved.

Summary

1. The transatrial approach to mitral valvotomy proved to be satisfactory only in those patients in whom the valve split easily.

2. Long-term follow-up of patients subjected to mitral valvotomy by the standard left thoracotomy, left atrial, approach revealed initial improvement followed by deterioration in about one out of three patients.

3. The inadequate mobilization of the valve would appear to be the major factor responsible in the failure of mitral valvotomy.

4. Transventricular valvotomy, accomplished by the use of a two-bladed expanding dilator provides much more adequate mobilization of the valve with no appreciable increase in operative risk.

5. This paper briefly describes the technique and summarizes the results that we have obtained in sixteen consecutive cases.

The Law and Medical Science

A new approach to the betterment of expert testimony in personal injury cases; systematic indoctrination in the proofs of science and the science of proof.

HUBERT WINSTON SMITH, LL.B., M.D.
Austin, Texas

Dr. Smith is Professor of Law and Legal Medicine; Director, the Law-Science Institute, University of Texas; Chancellor, the Law-Science Academy of America.

Justice can be achieved only in litigation, whether civil or criminal, if the facts found by judge or jury correspond with truth. There has been a constant search in this country, for many years, for solutions to the vexatious problems, multiple in nature, which spring from use of expert testimony. Thus, many states now permit by statute, or rule of court, appointment of impartial physicians or other experts, by the trial judge, to carry out impartial examinations of the claimant, in personal injury cases, of the accused claiming a mental defense in criminal cases, or of inanimate subject matter in some instances. Accompanying these broad discovery provisions, which have been so effectual as a part of the federal rules of civil procedure that they have been widely copied by the several states, have been liberal reforms, in most states, permitting the taking of depositions of parties and witnesses prior to trial. By thoroughgoing direct and cross-examination, qualified counsel can extract from treating and examining physicians, and other expert witnesses, the full facts as to what they did and found and force into the open the medical contentions which will be made, at the same time crystalizing, defining and restricting the issues. By assembling past medical and hospital records, and taking depositions of all the treating or examining physicians, the parties can define and limit the medicolegal issues at an early state of the litigation. Since the founding of the law-science movement in this country, which may reasonably be linked with the initiation of our law-science short courses at Tulane University in 1950, the percentage of personal injury cases disposed of by pre-trial compromise negotiation has risen from some 45 per cent to close to 90 per cent! Counselors are now quite willing to concede that it is important to use the best available specialists, and necessarily to exchange freely medical reports, without putting the opponent to the unnecessary trouble of taking depositions.

At the same time, there is a great unevenness in the quality of expert testimony in our trial courts, both in civil and in criminal cases. Only some six states of the union require a physician to be a certified specialist in order to qualify him to testify on a specialty problem. The field of medicine has now broken down into some thirty-five recognized medical specialties and the judge who permits the general practitioner to give opinion evidence on specialty subjects, would be the first to take the train for Mayo Clinic in event he had some serious health problem arise.

Some have assumed that the giving of unscientific medical evidence testimony is a badge of fraud, but it is my conviction, after studying the matter for many years, that ignorance is a greater foe of justice than misrepresentation. We need to tighten up our qualifications for expert witnesses, *en-voir dire* (the qualifying) examination.

While the treating physician should always be allowed to testify, whether he be a specialist or not, close control should be exercised to the end of determining important litigation, dependent upon advanced, skilled knowledge of a specialist, upon testimony of general practitioners.

As most readers will realize, the New York Academy of Medicine has recently cooperated with the trial courts of New York in supplying outstanding medical specialists, drawn from a rotating panel, to study particular cases in which the courts have applied for help. This is a step forward, and perhaps the gravest criticism which can be leveled at the plan is the fact that the trial judge customarily refers to this specially selected witness as the court's witness, thereby throwing the mantle of omniscience over him. This seems undesirable, and it would suffice if the court merely indicated that the expert witness had examined, without objection of the parties, with the understanding that both parties would be able to cross-examine him freely, permitting the jury to give his testimony deserved weight.

Another solution which has been coming forward at intervals in recent years, is a suggestion for abolition of trial by jury, and even for abandonment of trial of these cases by judges without juries. The contention is sometimes made that an administrative tribunal, not bound by the common law rules of evidence, could gain a special skill in handling such cases, and dispatch claims more expeditiously and justly. After studying this matter for a number of years, we entertain grave doubts as to whether such a mechanism would improve the current level of practice. Indeed, we are persuaded that adversary trial, when streamlined and speeded up, with full rights of direct and cross-examination of witnesses protected, makes for a more thorough preparation, and presentation of evidence than any other known mechanism for determining disputed facts. These conclusions of ours, based upon many experimental trials, where the proceedings and deliberations were tape-recorded, have been corroborated in recent months by research studies carried out by sociologists at the University of Chicago Law School, on trial by jury. It is my belief that the need of the times is to train law-science advocates—a new species of trial lawyer who is deeply grounded in the proofs of science and the science of proof. Certainly, the whole trial process must move forward to a scientific level, if trial practice is to survive in an age which demands objectivity and speed.

If I may say so, with proper modesty, the Law-Science Institute of the University of Texas, the Law-Science Academy of America, and the Law-Science Foundation of America, have been the chief leaders in developing authoritative scientific instruction for trial lawyers in this country. Together, they have conducted during the past ten years, more than forty national institutes, or short courses, and these have been attended by more than 6,000 lawyers and physicians from all parts of the United States. The Law-Science Institute of the University of Texas was the first such institute organized to carry out research and teaching between law and medicine. Indeed, its purposes are even broader, namely, to promote, by every proper measure, the integration of law with the physical, medical, psychological and social sciences. The basic premise is that law cannot abandon its historical heritage, but must subject itself constantly to extrinsic criticism of other intellectual disciplines, insofar as these are relevant to fact-finding, or policy formation. The day of intellectual isolationism is gone. The great need of the time is for synthesis of knowledge, using a multi-dimensional approach, and giving each distinct intellectual discipline which has a title to speak, an opportunity to be heard. As we view the progress of human knowledge, we may divide research into two varieties. One is primary, analytical research, in which facts are broken down, or fragmented, into even smaller facts, with the result that we pass from one universe of knowledge to another, constantly seeking final mechanisms, ultimate facts, or at least controlling basic principles. The other type of research, which has been much wanting on the American scene, involves the task of inter-relating bodies of knowledge. Such cooperation can result in improvement of justice, solution of many difficult problems which will not yield to the analysis of a single intellectual discipline, and establishment of valued judgments based upon an integration of knowledge and culture. One line of research cannot take the place of the other, but both must proceed concurrently. By its very nature, since law must assume to regulate every activity of mankind, law has a capital opportunity to become a master social science in this process of integration of knowledge.

Now, this need for integration of knowledge is particularly keen when we come to complex catas-

trophic injuries. Such injuries usually involve more than one organ system of the body and invoke the attention of several different types of specialists. In order to arrive at any fair judgment as to the fact and degree of injury and disability and vexatious problems as to whether the traumatic stimulus caused, aggravated or precipitated (or accelerated) the claimant's disease or death, we may have to relate various doctrines or substantive law with the contributions of several medical and scientific specialties, including the work of such non-medical men as clinical psychologists and physicists. The training given in American law schools today simply does not equip the oncoming young trial lawyer with the basic knowledge, or skills, to carry out this task of analysis and synthesis, which can be met only by a properly trained law-science advocate.

To meet this great deficit, two steps have been taken. The Law-Science Institute at the University of Texas has introduced ambitious instruction in "Legal Medicine and Elements of Medicolegal Litigation" for law students interested in trial practice. This is a course which meets four hours each week, and it is not unusual, though it is an elective subject, for approximately 100 of the students to take the course each year. Under our practice, the human body is divided into nine organ systems, the tenth area is reserved for medicolegal problems involving the total personality, and thus corresponding to psychiatry (and other behavioral sciences) and clinical psychology. The eleventh area is reserved for "Medicolegal Trial Technique." Students are encouraged to do collateral research, both in the Medical Library, on select subjects, and in the Law Library, in an effort to inter-relate relevant materials. The institute has been instrumental, through the years, in developing more than 170 published studies on important, frequently recurring medicolegal problems, and these have appeared in leading law and medical journals, indicating that the goal of basic English has been reached without making the material elementary.

In recent years, the Law-Science Academy of America, and the Law-Science Foundation of America have come to the aid of the Law-Science Institute in this tremendous undertaking, involving both continuing medicolegal education of practicing lawyers and physicians, as well as insurance company personnel, and others professionally concerned with medicolegal problems, and in developing ever-increasing instruction, by way of seminars, for the undergraduate law students.

The Law-Science Academy of America and the Law-Science Foundation of America are non-profit, charitable societies, so recognized by the department of internal revenue, which are devoted to the same broad purposes as the Law Science Institute, but specifically, at the moment, to furthering practical integrations of law with other fields of learning. The implications of this pragmatic movement can be tremendous. Obviously, there is a great need to integrate business practice with law, political theory and practice with law, economics with law, etc. One of the more challenging areas involves integration of behavioral sciences with law. It is our contention that only behavioral sciences can explain human behavior, and that only law can regulate it, and that therein lies the basis of a necessary and enduring partnership. The whole reformation for our antiquated criminal law and penology depends on the rapid acceptation of these premises. It is interesting to me that lawyers everywhere seem enthusiastic, rather than resistive, in connection with the proposed infiltration of law with relevant scientific materials. Recently, at one of our short courses held in New Orleans, the eminent neurosurgeon, Dr. James C. White, Professor of Neurological Surgery at Harvard Medical School, stated that he found the lawyers to be more avid students of medicine than the medical students and doctors themselves. On all sides, we see a quickening of interest among lawyers in this trend toward a multidimensional approach to legal thought and action. Spearheading this national movement, has been the Law-Science Academy of America, which has advanced from a membership of ninety, some two years ago, to some 700 leading lawyers and physicians in this country today. Every lawyer and physician in good standing, who is motivated toward the purposes of bettering social conditions, including the administration of justice, through cooperation of law and science, is eligible for membership. Various grades of membership exist, and various types of honors may be won on the basis of concrete achievement.

The current president of the Law-Science Academy of America is Dr. A. Earle Walker, Professor and Chairman of Neurological Surgery at Johns Hopkins Medical School, generally recognized as one of the leading research men and clinicians in his field. Recently, he returned from London

where he served for a month as Professor of Neurological Surgery at Guys Hospital. Current chancellor of the Law-Science Foundation is Dr. Herbert C. Modlin, senior psychiatrist at Menninger Clinic and Foundation, widely esteemed as the leader in the behavioral sciences, and generally accepted as one of the foremost exponents of integration of behavioral sciences and law. Dr. Hubert Winston Smith has been elected lifetime chancellor of the Law-Science Academy and as lifetime president of the Law-Science Foundation, and gives administrative continuity, in conjunction with the Boards of Trustees, in development of the ongoing programs of the two organizations.

In their determined efforts to hasten the training of an adequate, elite corps of Law-Science advocates in this country, the Academy and Foundation have established a unique summer instructional program in Crested Butte, Colorado, once a bustling mining town, 30 miles from Aspen. When the Colorado Fuel and Iron Company closed its mines, in about 1953, the population dwindled markedly, and for a time, there was a real risk that the village might become a ghost town and undergo continuing dissolution. Three years ago, however, the Law-Science Academy purchased Old Union Hall, a large two-story structure in Crested Butte, and completely remodeled it, in keeping with the spirit of the town. Last summer, the Academy held its first summer teaching effort there, offering four individual weeks of instruction, featuring top medical specialists and trial lawyers of this country. This year, the instruction was stepped up to nine weeks, running from June 13 through August 12, 1960. Each week of the instruction is a separate course, but there is an inter-linking continuity which makes prolonged attendance highly beneficial to those who can stay for longer periods.

In keeping with the idealistic purposes of the Law-Science Academy and Foundation, printed announcements were mailed to every Law Dean in America, indicating that carefully selected students would be eligible for scholarships at Crested Butte. It is hoped that a big brother relationship can be established between the distinguished visiting physicians and trial lawyers, on the lecturing staff, and the embryonic trial lawyers. It is possible, in the beautiful, restful setting of Crested Butte, to carry out instruction on an informal, seminar basis with maintenance of maximum arousal, interest and participation by both students and lecturers. A wealth of audio-visual material is used. On two evenings, the great trial lawyers of the country conduct three-hour seminars on "Medicolegal Trial Technique."

The Law-Science Academy has recently purchased an adjoining building which will be converted into an incomparable Law-Science Library. The goal of the Law-Science Academy and Foundation extends even further than the mere integration of law and medicine. It is hoped that a unique cultural center can be established at Crested Butte, where unusual, creative individuals in all the arts and humanities, can spend time together and receive stimulation from fields other than their own.

Thus, it is anticipated that, eventually, those who come primarily for law-science training, and incidental family vacation activities, will have a variety of choices, in the late afternoons, or evenings, to attend such cultural activities as: a great book series; teas devoted to discussion of literature, art and painting; politics; economics; art appreciation; and a host of other subjects calculated to be of deep interest to the inquiring mind. Thus, the dream of Crested Butte, is not only to sharpen those who come, but to broaden them. Situated in a valley surrounded by towering mountains, Crested Butte has been acclaimed as one of the most beautiful spots in North America. Both lawyers and physicians being diversified in their intellectual interests, with predilections toward various arts, sciences and humanities, and their preliminary preparation for their professional careers, so that Crested Butte's visiting guests are likely to have ranging interests. Already ambitious steps are under way to fashion a plan for this cultural development. Those who have been captivated by its charms have already rechristened "Crested Butte Mountain" the "Magic Mountain." Academy members plan, in future days, to have winter meetings there, as well, which will be combined with winter sports, skiing, sleigh riding and playing in the snow.

Running concurrently with the teaching plans at Crested Butte is an ambitious publication program, now in its formative stages, designed to create criteria of proof in respect to the relationship of trauma to injury and disease. These will involve participation by the most eminent living medical authorities, as well as distinguished trial lawyers, and are expected to be issued in monograph form, beginning at an early date.

Blindness

A Vital Challenge to the Professional Team

There are 18,000 blind and visually handicapped people in Minnesota. Our cultural attitudes of rejecting, feeling benevolent towards, or rationalizing over an act of nature in blindness, have gradually evolved towards a new approach of rehabilitation and integration. As state director of Services for the Blind, the author reviews the spectrum of blindness and its challenge to modern medical practice.

THE PERSON who is faced with or has experienced the loss of his sight is troubled by two major concerns—of one of them he is very much aware; he desperately wants to see again. When this is medically possible, his problem is solved. This paper concerns itself with the treatment of the person who is destined to live his life with partial or total blindness and his deep struggle with what this means to him.

The physician has too frequently assumed that a hopeless physical prognosis concludes his professional relationship with his patient. I should like to assert during the course of this paper that this is not quite so. I am not a physician. Yet, I have found it expedient and necessary to learn considerable from those of you who are in order that I might function with deference to your patients'—my clients'—physical needs. I am a psychologist and it is my professional responsibility, and that of my colleagues in education and social work, to apply effectively the best knowledge and pertinent insights of our time to the personal, social and vocational improvement of blind persons. We welcome this opportunity to share with you current thinking from the social sciences relative to the handling of this disability which you may find useful in functioning with deference to the patient's social and psychological needs and in assisting him to secure an opportunity to rebuild a useful and gratifying life.

The Individual and His New Experience

The physician is usually the first professional person to consider the patient's needs. A pattern is well established in Minnesota in which visually impaired persons discovered by State Services for the Blind and our cooperating agencies require immediate referral to the family physician and the ophthalmologist of the patient's choice. Increasing numbers of our clients are referred to us by physicians, but many others are discovered and referred to us from a variety of other sources after they have struggled with blindness for many years and perhaps consulted their physician many times. In my judgment, the physician's imperative role is not fulfilled until he has arranged for or referred the patient with educational, social or vocational needs to appropriate services which lie beyond the direct orbit of his practice. Some of these needs derive from obvious and others from subtle sources. Some are clear to the patient, while others lie below the surface of his awareness. In a new and strange environment, needs can be related only to the hazards and possibilities which it holds. The blind person has lost only one of his attributes. In this strange new world, his behavior will be conditioned substantially by his previous experience and the many other personal characteristics which he brings into it. This is to say that persons vary in their capacity to tolerate negative experiences. This is also to say that the depth of anxiety and depression

C. STANLEY POTTER, M.A.
Saint Paul, Minnesota

Read before the Minnesota Academy of Ophthalmology and Otolaryngology, November 13, 1959.

Mr. Potter is Director of State Services for the Blind, Minnesota Department of Public Welfare.

and whether it is overtly expressed, contained or disguised will be determined chiefly by the following factors: (1) personality, maturity and socialization, (2) intensity of special interests and aptitudes, (3) nature of motivational values and (4) status security concepts.

The Patient May Be Sensitive

The physician is usually consulted rather immediately after the patient has become aware of his disability, or with children, when the parent becomes aware of a severe malfunction. The patient is likely, at this time, to be highly sensitive, anxious and uncertain and, thus, psychologically highly vulnerable to suggestion. He will seek clues to his future, not only in the physician's words, but in his manner. He may interpret and misinterpret in his desire to determine whether his physician holds out any hope for him, and at this point, hope to him means the capacity to see again. If he develops an ill-founded impression that his lost capacity may be restored, he may, as many have done, spend his life and his resources and those of his family seeking an ever-elusive cure. If, on the other hand, he is faced with the futility of such a hope, he will often be in desperate need of understanding and insightful assistance in reconstructing his life. Without this, he will assume the unhappy and devaluating role ascribed to blindness by the stereotype of this condition, still strong in our culture.

The problems faced by blind and visually impaired persons are, perhaps, most meaningfully examined by distinguishing between those limitations of performance inevitably implied by the inability to see and those, usually the more damaging functional (psychological sense) or psychosomatic barriers, which limit social and vocational effectiveness and personal tranquility.

In working with visually impaired persons, an awareness of the difficulties they are experiencing and a familiarity with current philosophy, methods and resources, most appropriate to their educational, social and vocational development is of essential usefulness.

Practical Effects of Visual Isolation

Blindness and deafness are the great sensory cripplers of man. Impairments of taste, touch and smell are rare as primary conditions and seldom disabling. It has been rather well established that 85 per cent or more of the sensory experience of non-handicapped persons is visual. It is immediately apparent then that blindness places its victim in substantial isolation by interfering with the flow of information from the outside world to the brain. Blindness is then (1) an *informational handicap.*

The eye is an organ of expression. It is often considered more subtle and more fluent than the tongue. A seeing person seldom speaks without establishing his audience by visual contact first. Blindness is then (2) a *communication handicap.*

A seeing person orders himself in his environment by visual cues. He knows where he is by observing the way he has come. He identifies those about him by appearance, manner and dress. He determines the appropriateness of the clothes he wears by observing himself. He selects, locates and guides his food to his mouth with visual cues. He

maintains his direction and protects himself from collision as he moves about by visual observation. Blindness is (3) a severe *orientation handicap.*

This set of very practical limitations is quickly felt by every newly blinded person. They are unique to blindness. No set of hopeful sounding cliches, such as are often widely applied with every good intention to the problems of all handicapped persons, will alleviate these severe barriers to performance one bit. Only the persistent effort of individual blind persons, combined with the most diligent application of multi-discipline knowledge which we can co-operatively bring, has any genuine meaning.

The Physical Versus the Functional Problem

Before discussing current approaches, we will consider for a few minutes the nature and the origin of the functional by-product of blindness which arises from human rather than nature's error and is the more defeating. The child who grows up without his sight develops a rather accurate notion about the meaning of his loss by the time he is six or eight years old. Yet, this insight does not compare in destructiveness with the role into which he is frequently forced in which he is used to meet the emotional needs of unthinking persons around him—usually adults. He must be "the poor child," "the brave child"; he must submit to sincere acts of consideration, which he often doesn't need, and he must at times be the object of demonstrations which adults assume in order to impress one another. He has much too frequently been removed from his home and community for educational purposes even though in many instances this is not necessary. The blind child with good parents who will be allies in facing his problems needs them very much as does any child.

The adult who traumatically loses his sight soon finds that the devastation that grips him is not nearly so related to his new inability to perceive the world about him at a glance as it is to how his family and his associates will look upon him as a blind person. He worries about his marital relationship, the attitudes of his children, the loss of his friends and his job. Individuals vary widely in their capacities to assimilate negative experiences. Our concern here, however, is with the fact that the reason for the depression which follows the onset of blindness almost invariably will rapidly become focused upon personal depreciation, specifically around inter-personal relationships and social and vocational acceptance rather than around the direct effects of the physical function which is lost.

History Inhibits Blind and Seeing

Society's attitudes toward deformity are grounded deep in our culture and have moved through four principal stages and, although the pattern is similar toward all readily observable physical deformities, the frequency with which blindness is discussed in both religious and secular, ancient and modern literature leads one easily to the belief that through the ages it has concerned and disturbed man more than any other abnormality.

In an elementary culture in which each individual had to meet nearly all of his own needs by his own devices, a blind person could not survive. Since blindness meant death, it was greatly feared. The birth of a blind child soon became an omen of evil upon the mother and family, with feared religious meaning. Such children, and their mothers with them, were often destroyed.

With the rise of the modern religions, the old attitudes toward blindness and methods for dealing with it were recognized as inhumane and incompatible with the new ethic. The many biblical references to blindness frequently equating it with sin, disease and poverty in the beggar's role call for compassion and pity. They establish the blind person's right to live, though only at the material benevolence of other men.

Blindness made a deep impression, however, and in time there were many persons who felt a logical necessity for attempting to square the compassion and the justice of God with the apparent injustice suffered by blind persons whom they observed. This led to commonly accepted rationalizations which attributed extra sensory perception as well as the notion that blind persons were compensated by more acute senses of hearing and touch, cleverness, musical gifts, etc. Still others explained that blind persons were appointed by God to remind other men of how fortunately they had been blessed with the capacity to see. These strange views were further isolating. We may say then, that the first three attitudinal stages toward blindness were (1) rejection, (2) benevolence, and (3) rationalization. The first denied him life; the second denied him hope; the third denied him fraternity. Each step of the way the new attitude

was added to the old; it did not replace it. All are reflected in our culture today. Most people carry segments of these feelings below the surface of their awareness and for this reason, when they meet a blind person, may feel uncomfortable. The intensity of this experience is likely to depend upon the suddenness and closeness of the relationship. Whether these feelings are fleeting or permanently bar interpersonal relationships is dependent primarily upon whether the blind person feels awkward, and is chronically disturbed about his condition, or whether he has had and been able to use opportunity to grow beyond the pervasion of his personality by blindness, and sees himself as a whole, complete and effective person. We believe that today's approaches to the rehabilitation and integration of the disabled person reflect the fourth and newest of society's attitudes toward blind persons.

Four Steps in the Rehabilitation Process

We may consider the rehabilitation process in four steps which are designed to reduce both the physical and psychological damage of disability and permit the individual to bring himself to maximum usefulness and dignity.

1. *Prevention.*—If we can prevent a disability or halt the progress of disease early through public education and public screening, we have obviously accomplished the most desirable goal. Half of present-day blindness is preventable according to the National Society for the Prevention of Blindness. If we can create in the public mind a modified, more accurate and more healthful picture of the comfortable and participating blind person, we will go far in preventing the emotional damage to both blind and seeing persons which we have discussed as the cultural image.

2. *Restoration and Alleviation.*—When disability strikes, medicine is obviously the first line of defense. The most significant service that can be provided any person is, of course, to restore the capacity which he has lost or alleviate to every feasible degree its damage. We are interested in general physical health as well as eye pathology since additional problems are frequently uncovered which, without attention, may lead to multiple handicaps. At this stage, too, we are concerned with early emotional involvements. The newly blinded person may assume that the whole course of his life is changed. The entire structure of aspiration and motivation which he has constructed from childhood, the foundation of his life movement and mental health frequently crumbles rapidly. Rehabilitation services can often be of substantial assistance in confining these changes of self-concept to those actually and necessarily imposed by the disability.

3. *Compensation.*—The mastery of a vast body of skills involving the efficient use of the other senses in collecting information, in communicating and in orienting to the world are essential to the blind person who would minimize his problems. Compensation also involves the development of new interests and activities to replace those which may have been rendered less pleasurable by blindness and often some new attitudes. Dependent upon whether the disability is total or partial, new methods for accomplishing old tasks may include dressing and feeding, braille and typing, travel training and physical orientation, social relationships and many other personal skills. Compensation also takes the form of vocational and homemaker training.

4. *Accommodation.*—At this step in the rehabilitation process we are anxious that the blind person recognize those aspects of his disability which remain as a personal liability—untreatable, uncompensable. Every blind person has them but it is important that he look at them for what they are; that he no longer allow blindness to pervade his personality and interfere with his movement toward life; that he sees blindness as one of a multitude of personal characteristics. He need not like the blindness but as he sees himself in total, he should find normal self-esteem and confidence.

Prevalence of Blindness in the United States and Minnesota

Estimates of the total number of partially seeing and blind persons in Minnesota and the nation are based upon sample studies. In the United States they vary from 350,000 using the common 20/200 definition of blindness with best correction (Hurlin's Projections[1]) to 960,000, using as a definition the inability to read newsprint with correction (National Health Survey[2]). Hurlin's estimate for Minnesota is 1.9 per thousand or approximately 6,500. University of Minnesota studies[3]

estimate the total blind and visually handicapped population in Minnesota as 18,000. Previous studies suggest a ratio of 4 to 1 partially seeing to blind or 32,500 visually handicapped persons in Minnesota. Eight thousand visually handicapped, 4,000 of whom are legally blind, are known to State Services for the Blind.

Rehabilitation Services Available

Blind or partially seeing persons may be referred for service to county welfare departments or to State Services for the Blind and Visually Handicapped. Services available include counsel and information for parents with pre-school blind and visually handicapped children, special education, planning and placement carried out in co-operation with local superintendents of schools and the Division of Special Education who have prime responsibility for the educational placement and instruction of handicapped children except for those requiring residential school enrollment.

My colleague, Mr. Bourgeault, discusses the challenging and rapidly developing educational programs for blind and partially seeing children in the accompanying paper. Adolescents and adults may be referred for the broad scope of personal adjustment and rehabilitation services previously discussed. In Minnesota we are fortunate to have skilled state workers and a unique regional rehabilitation center sponsored by a voluntary agency, the Minneapolis Society for the Blind. St. Paul and Duluth also have voluntary agencies for the blind providing primarily sheltered employment. Emphasis is placed, however, on the use of regular community services, trade and vocational schools or colleges for vocational preparation as soon as the individual is ready for competitive experience. State rehabilitation counselors assist these agencies as necessary.

We are interested, too, in the problems of aging blind persons in their own homes or in nursing homes. Age and blindness both carry dependency connotations in our culture. The connotation of the two combined often leads to dependence and feelings of uselessness far beyond the point of necessity. An able worker can help the blind person and those about him retain his independence.

Financial aid is available for needy blind persons while talking books and a host of other aids, devices and services are provided to those who desire them.

Low Vision Optical Aids

Low vision optical aids and devices are becoming more frequently important in the rehabilitation process. We are anxious to encourage interest in their careful application. These devices do not generally improve total visual efficiency but they frequently convert it to usefulness for specific tasks and activities. We believe that the proper application of low vision aids is a problem which frequently requires interdisciplinary co-operation since the following kinds of information are required to determine the nature of the device needed and predict whether it will be used by the patient. (1) What specific tasks does the visually handicapped person wish to perform and is he correct in assuming that inability to see is the inhibitor of his performance? (2) Are his specific interests sustained or are they likely to be transitory? (3) Does he have both the abilities to use the device properly and to accomplish the tasks in which he is interested? (4) Does he have the motivation and stability to tolerate the inconvenience and frustration associated with caring for, keeping track of and using the additional device, (5) Does he have the self-sufficiency to use the device in the presence of others without undue sensitivity or embarrassment? Low vision aids, that is, magnification or other corrections prescribed in amounts and for distances to permit or facilitate the performance of specific rather than general and customary tasks find their most successful application in (1) the solution of vocational problems, (2) their use with more mature children in classroom work and study and (3) their assistance to persons with strong specific avocational and personal activity interests.

Summary

During the last two and three decades we have moved toward vocational specialization at an ever increasing pace. It is obvious in the professions that this is so. It is also apparent that it is true of nearly every facet of vocational endeavor and has come to typify the character of our existence. This is fraught with vast significance for the person who must live with an impairment because it means that by pre-selecting those areas of activity in which his disability will not inhibit severely his productive effort, he may live and he may compete successfully with the non-handicapped person. We live in a fast moving, fluid, changing world. New

ideas are readily accepted. Opportunity to bring the hope of rehabilitation and satisfying life experience to each blind person is greater than it has ever been. We need to look to this task with the knowledge that it is urgent so that we grasp it while it is with us. Our challenging problem is to change and change rapidly the expectancy role for blind persons in our culture.

Although we may look toward efforts at public education to help, the greatest impact will be made as more and more blind persons function competently and effectively and constantly relate to other men. Anyone who has known personally just one effective, productive, comfortable blind person soon loses the inhibitance to his acceptance. He soon ceases to see the single characteristic of blindness as a pervading mark of identification. We have said that society is more ready and more able, for very practical reasons, to assimilate disabled persons than it has ever been. But there is a great chasm that divides the inhibition, the rejection, the depressing pity and benevolence and the strange rationalization of the past from the possibility of the future. The physician, psychologist, social worker and educator, even though sight may not be restored, may hold out hope to the parent for his child, to the child for his future, to the adult for a fruitful and satisfying life experience. We may, if we pool our resources, build a bridge of successful rehabilitation through co-ordinated medical, social and vocational treatment.

I want to pay a moment's tribute to Dr. Frank E. Burch who, in his retirement, visited our offices a number of times in the continuing pursuit of his interest and study of the productive rehabilitative capacities of visually handicapped persons.

I would recognize, too, Dr. Charles E. Stanford whose contribution as consulting ophthalmologist for State Services for the Blind since 1937 has been of substantial significance in the development of a carefully conceived, sound state program. We shall miss Dr. Stanford in his retirement.

We are appreciative of the efforts of Dr. Hugh Monahan, Chairman of the Academy meeting when these papers were first presented, and who serves as consultant ophthalmologist for the Division of Special Education. His work in both glaucoma and pre-school screening, along with the many other ophthalmologists who are contributing beyond the requirements of their practice, to the improvement of the visually handicapped people of our state is widely appreciated.

A word of friendly gratitude to Drs. William Wenner and Joseph Gaida, both of whom I have seen peering at me from the other end of an ophthalmoscope many times.

It is possible that physicians may wish to pursue our subject further. A recent publication, "The Role of the Ophthalmologist in the Rehabilitation of Blind Patients," published by the American Foundation for the Blind, 15 West 16th Street, New York 11, New York, is the report of a survey of ophthalmologists' opinions and practices relative to their outlook for the blind patient, their advice to him and their referral of him for other forms of rehabilitative assistance.

A study entitled "Rehabilitation Resources in Minnesota," sponsored by State Services for the Blind and the State Division of Vocational Rehabilitation, at the request of the Governor's Committee on Vocational Rehabilitation, will be released shortly. Each practicing physician in Minnesota will be supplied a copy of this handbook to rehabilitation services for impaired persons.

Substantial material relating to the problems of children and parents, the adjustment of blind persons, vocational rehabilitation and prevention of blindness is available upon request through State Services for the Blind, 117 University Avenue, St. Paul 1, Minnesota.

It is with both hope and confidence that we look to a future in which blindness will represent to the individual and to society only the personal inconvenience which, by its nature, it is. This will be true when we have forgotten the limiting barriers which the ages have built of unreality and misconception. In the light of today's perceptions and the efforts of the disciplines toward co-ordinating their human problem solving skills, new opportunity for life fulfillment should come to ever increasing numbers of impaired persons within our generation.

A Continuum of Educational Services for Visually Impaired Children

Pediatric eyesight is not "normal," "visually impaired" or "blind." There is a continuum of disability requiring a continuum of educational services for the disabled child. Segregated programs have given way to integrated co-operative programs. Present-day guidance is for true rehabilitation, often using itinerant special teachers.

STANLEY E. BOURGEAULT, M.A.
Saint Paul, Minnesota

Read before the Minnesota Academy of Ophthalmology and Otolaryngology, November 13, 1959.
Mr. Bourgeault is Consultant, Special Education Section, Minnesota Department of Education.

IN TRACING the evolution of educational services for visually impaired children, from its original "segregated" nature through the most sophisticated of the present combined resource and itinerant types of services, it is necessary to speak of both strengths and weaknesses of each stage; surely, the past and all its experiences has provided those of us working in the present with many of the foundations of our existing culture.

As a preface, permit me to correct several misconceptions.

First, the medical profession has shown us that there are few instances in which we, as educators, may literally help to "save sight." Therefore, I will not speak of programs of "sight-saving," but rather, of educational programs for visually impaired children.

Second, educators of such children have found repeatedly that the amount of special service required by a child is not necessarily proportionate to or dependent upon the extent of the visual impairment. We maintain that the programming needs of a child are not described by a medical diagnosis and statement of distance vision alone. One child considered legally blind may read regular print in regular books and enjoy almost identical academic pursuits as his classmates with "average" vision. Another child considered legally blind may require instruction through braille and other tactual media provided by a specially trained teacher. And it is increasingly apparent that the interrelated, variable, and dynamic nature of extent of disability in relation to extent of impairment is so complex that no single discipline can possibly evaluate and/or establish appropriate programs of service.

Third, many educational programs are classified as "classes for the blind," or "classes for the partially seeing." This seems to be too gross an approach to highly individualized pupil needs. To be sure, there are varying kinds and amounts of service, but continued dichotomy between blindness and partial sight clouds the issue of individual difference. Failure to recognize loss of vision as a broad continuum, as merely one dimension to be considered in the over-all measurement of the extent of disability, is to foster gross, inaccurate, and damaging concepts—for educators, for laymen, for family, and of greatest import, for the child.

I will discuss, therefore, programs of educational service to "visually impaired," rather than classes for "sight-saving," and I will refer to the "continuum of visual impairment," rather than to the "blind" or to the "partially seeing." We must necessarily accept arbitrary determinations of disability for legal and other purposes. At the same time, we must in every way encourage the development of a philosophy—a cultural attitude—in which a child with a visual impairment may fall at a place along the continuum of disability, not by acuity alone, not by legal definition, not by stereotyped or arbitrary labels such as "braille reader" or "clear-type reader," but rather, in a multi-dimensional manner which reflects a greater

degree of understanding and professional sophistication than existed a century ago.

Historical Development

One of the first methods of meeting the educational needs of visually impaired children was the *segregated* program. Limited experience and cultural responses to visually impaired individuals over one hundred years ago compelled well intended persons to move the children together—and often away. There can be no question that such a method was a major step forward in recognizing that the children were responsive to education. It was the first, and will always remain a most significant, landmark in the evolution of educational services.

The development of segregated programs for visually impaired had parallels in the development of "institutional" types of programs for children with other disabilities. Because the development of segregated programs for auditorily impaired children approximated the development of programs for visually impaired children in time, for example, many misconceptions about similarities in educational methodology developed, and remain with us yet. It is harmful and inappropriate to generalize about special needs of "handicapped" children.

The end of the nineteenth century brought more recognition of the varying needs of each child, culminating in some excellent research in child growth and development around the early years of the twentieth century. At that time, the "segregated" or institutional type of program made serious and well intended efforts to modify its program, to bring its children into closer contact with "society."

The segregated program still exists as one of a variety of services in some states; it remains as the sole method of service in others; and it has been rarely used in still others. It would be unrealistic to assume that a total program of education services to visually impaired children could exist without the contribution which can be made by segregated programs under highly individualized and often unique circumstances.

As general educational procedures gradually changed, our conception of the handicapped child in the regular school program changed as well. Educational research and refined teaching skills, medical research and improved medical services gave impetus to the changing cultural reactions toward the visually impaired child. Educators sensed their responsibility, along with other professional groups, to do all possible to eliminate or reduce the limiting self-misconceptions of the handicapped individual. Measurement techniques and our ability to compile and interpret data continued to improve so that highly individualized educational programming for all children, with or without remarkable disability, became the American creed.

As early as 1919, three of Minnesota's major cities were reacting to the change in public understanding. Typically, demography played a role in the development of special services. Several eastern cities had demonstrated conclusively that with a sufficient population of children in a specific disability area, local programs could be developed, retaining the advantages of permitting a child to remain in his own community and of growing up knowing his sighted peers with whom he would ultimately share civic responsibility. The integrated *co-operative* program was initiated. This program, in which the child identifies with the special teacher, in which the special room serves as his homeroom and from which his daily education plans stem, also has some advantages under highly individual circumstances.

Early criticism of this type of program had some foundation. It was true that the children were merely attending smaller "segregated" programs, but greater opportunity for observation within the community aided in the increased recognition of similarities rather than differences between visually impaired and sighted children. It seemed less and less logical to provide parallel but non-integrated educational classes. Why should visually impaired students remain separate from their sighted peers if each could profit from similar, if not duplicate, educational experiences?

As new co-operative programs were initiated, there was increased emphasis on the extent to which the handicapped child was "permitted" to participate with the sighted child. Eventually, there were over a half dozen cities in Minnesota in which the visually impaired child might remain at home while acquiring an education which was essentially a duplicate of and was provided as frequently as possible with his sighted counterpart. Ability to integrate, however, was sometimes based on criteria or behavioral phenomena which were not necessarily related to visual disability, *per se*. Too frequently, the extent of participation with the regular class was dependent upon the attitude

of the regular classroom teacher—the visually impaired child being admitted merely as a "visitor" rather than a regular member of the class.

The semi-integrated, or co-operative, plan remains today in several of our cities. For many children, however, it still leaves something to be desired. The Department of Education, though it recognizes the nature of program change and appreciates the administrative time required to adjust programs for individuals, nevertheless holds that this type of program establishes or fosters child-community relationships which are totally incompatible with our philosophy of child growth and development and are not necessarily in the best interests of most children. For a few, this type of dependency relationship with a special teacher is a necessary developmental phenomenon; for many, from the very beginning of their education, it is a stifling and unnecessary self-concept distorting process. We are becoming increasingly aware that the extent to which a child with a visual impairment can be made independent will be in a sense a measure of his possible effectiveness in meeting the exigencies of life.

One major weakness in the co-operative program has nagged at the conscience of the special educator for many years. This system deprived the regular classroom teacher of an opportunity to know the visually impaired child as a full time member of our society, to recognize that he must be brought up together with non-handicapped children at all times, not merely when convenient. To eat together or to sing together were simple, acknowledged achievements; but learning to read seemed to be a completely separate thing. Too few regular classroom teachers have had the privilege of discovering that the child who must learn to read with braille books experiences the same developmental reading process as the child who reads print. The primary difference, of course, lies in the nature of the instructional material and not within the child or in his learning process. All things being equal, braille reading provides no major mysteries for a child who needs this method. In other words, we know from our experience that the child with impaired vision cannot summarily be placed upon a special continuum or special dimension of learning processes or of development of ego strength, or of "growing up" in general.

Teachers of co-operative programs were among those who recognized the tremendous advantages of having a child with a visual impairment placed with the regular teacher and with sighted children for increasing amounts of time during the school day.

As the child's opportunity for integrated socialization experiences increased, educators came closer to an understanding and a possible resolution of one of the major problems—of reducing the tendency toward development of feelings of dependence, and substituting feelings of independence. A child who oscillates daily between two cultural frameworks cannot be expected to achieve the same degree of independence and self care as a child who is introduced immediately and continuously into a real situation in which existing cultural attitudes are reflected and can be immediately interpreted.

We have seen thus far that there are elements of a segregated type of experience which, for selected purposes, may meet a very real need. In addition, we find that the co-operative program, which developed as a result of the parental desires to retain the family unit, has enabled school districts to meet additional requirements of visually impaired students. Such programming, while an improvement over very early efforts, was not the final answer.

Recognition of many of the problems of previous programs precipitated the development of the *resource plan,* which is a fully integrated program. In this system, the child's program is planned co-operatively between his regular classroom teacher and the specialist who is available when needed to present technical assistance and instruction. The resource plan has become increasingly popular and at present is one of the acceptable methods of programming for children with visual impairments in the state of Minnesota.

The regular classroom teacher understands that the education of the visually impaired pupil is as much her responsibility as is each of the other children assigned to her room. In addition, the talents and skills of a highly trained special teacher who is competent in all areas of instruction, who is able to instruct in braille, typing, use of slate and stylus, and who is familiar with other special devices and apparatus which are peculiar to the academic pursuits of visually impaired, are made available. The specialist provides such instruction not as the one who maintains foremost responsibility for such children but as a "resource" to the regular classroom teacher and the child.

The major strength in this program is obvious. A significant and continuing opportunity exists for the visually impaired child to develop a major identification with his sighted peers. As this is achieved, we see dramatic differences in the manner in which he reflects his growing confidence. We note his self-concepts developing with a minimum of distortion and dependency. We find at the same time that within this framework it is quite easy and acceptable for a child with special need to draw a parallel between himself and another child in his room who may require the special services of the speech correctionist, or another child who is being seen by an itinerant teacher of lip reading and auditory training. Furthermore, it is reasonable and not unique for him to excuse himself from the classroom on a definite schedule, or perhaps under certain circumstances at his own discretion, to seek out support or special information or to use some special tangible apparatus which he may require in order to independently pursue his studies. There is an advantage in placing resource rooms and resource teachers in carefully selected elementary buildings throughout a school district. In this manner a greater number of visually impaired children can come to the building which would ordinarily service their educational needs were they not handicapped.

The need for special instruction is greater during the primary grades, in contrast to a greater need for unique dimensional equipment and experience as the pupil grows older. Such a change is essentially in the nature, rather than in the amount, of special help.

The junior high school pupil is generally competent in such things as use of slate and stylus, typewriting, use of the braille writer, and has the ability to understand and use the braille code effectively for most reading purposes. The major contribution of the special teacher at this time lies not so much in actual participation with the child in developing skills as with the preparation of materials which enhance the task of the regular classroom teacher as she fulfills her responsibility in educating the visually impaired child.

By the time he is in a junior high school program, the disabled child may function quite independently, but will continue to require access to bulky reading and reference material and/or tangible apparatus such as tape recorders, regular typewriters, braille writers, et cetera. If the student is adequately prepared and sufficiently independent in study skills, however, he may require only occasional, rather than constant, special teacher services. The special teacher might visit the child's school on a definite schedule, or perhaps be available on call, moving from building to building within a school district or among several school districts. This type of special education service is called the *itinerant program.*

In several cities in Minnesota we presently find a resource room in the primary grades coupled with an itinerant type of service on the junior and senior high school level. A combination of several "types" of programs within a small school population imposes a tremendous responsibility upon the special teacher. She must arrange her schedule so that she brings service to a child at an appropriate time with minimum interruption of his regular school activities. The efforts thus far have been rewarding, and we anticipate an increase in this kind of service as the greatest number of the retrolental fibroplasias move out of the primary grades into the junior high school level.

The stereotyped "handicapped child" of a hundred, fifty, or even twenty-five years ago has become an illusion. No single discipline, no single corrective method, no single type of education program can possibly be equally appropriate for all visually impaired pupils.

I have presented some of the strengths and weaknesses of the various educational programs for services to visually impaired children in their developmental sequence. It would be as undesirable to say that everything was wrong in the beginning as it would be to suggest that everything is perfect now.

The positive elements of the *segregated, cooperative, resource,* and *itinerant* services must each be molded into a total comprehensive program which is sufficiently flexible to meet the needs of every visually impaired child regardless of where he falls on the continuum of disability. The dynamics of behavior are no longer mere postulates; they are fact. If we accept this we must also provide for the changing needs of an individual child in addition to the variety of needs of many children. The development of educational programming which meets every child's needs in relation to the community is a privilege which is accompanied by tremendous responsibility—not for the educator alone, but for the entire team of specialists.

Metastatic Malignant Melanoma Involving Both Ovaries

Report of a Case

Although a variety of metastatic tumors invade the ovary rather frequently, the appearance of ovarian metastasis from a malignant melanoma is extremely rare. The pelvic metastatic tumors in this case did not appear until seven years after removal of the primary lesion, which was on the leg. The malignant cells apparently reached the ovary by retrograde lymphatic permeation.

KENT W. BARBER, Jr., M.D.
MALCOLM B. DOCKERTY, M.D.
JOHN M. WAUGH, M.D.
JAMES S. HUNTER, Jr., M.D.
Rochester, Minnesota

DECISION to report the following case was stimulated by encountering a patient who had metastatic malignant melanoma involving both ovaries seven years after removal of the primary lesion. The literature concerning metastatic ovarian cancer is replete with reports dealing principally with Krukenberg's tumors, which originate from the upper part of the gastrointestinal tract. In a survey at the Mayo Clinic of surgical cases seen from 1939 through 1949, a total of fifty-nine of 531 ovarian tumors (11 per cent) proved to be metastatic; only 20 per cent of these fifty-nine cases represented the Krukenberg lesion.[1] More recently, the percentage of metastatic ovarian neoplasms has increased appreciably owing to the advent of oöphorectomy in the palliative treatment of advanced mammary carcinoma. Unilateral or bilateral ovarian involvement has been found in more than 40 per cent of this group of patients whose ovaries have been subjected to careful microscopic scrutiny.

None of the surgically resected metastatic ovarian tumors observed in the afore-mentioned period were melanomas, and necropsy studies on eleven of our patients with generalized malignant melanomatosis have not revealed any instances of secondary ovarian involvement.

The literature likewise attests to the rarity of metastatic ovarian melanomas. Basso,[2] in 1908, was able to find only five examples in addition to one he reported. Since that time five similar cases have been reported.[3-7] In two of these five cases, the primary lesions were in the eye. In several instances, the ovarian tumors were thought to be the primary lesions until necropsy disclosed their metastatic nature.

Report of Case

A thirty-nine-year-old white woman (gravida IV, Para II) entered the hospital in August 1959, with a history of "lumps" in the left scapular region and in the left side of the neck for one and four months, respectively. She had been in good health except for recent complaints of lower abdominal cramps associated with two to eight loose bowel movements per day. These cramps were relieved by the bowel movements.

Wide excision of a pigmented mole from the calf of the left leg had been done in February 1952, after the birth of her second child. This mole was discovered during

Doctor Barber is a Fellow in Surgery, Mayo Foundation; Doctor Dockerty is from the Section of Surgical Pathology; Doctor Waugh is from the Section of Surgery; and Doctor Hunter is from the Section of Obstetrics and Gynecology, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

routine postpartum examination. The defect was covered by a skin graft. Pathologic examination revealed a malignant melanoma measuring 1.5 by 1.5 by 0.3 cm. Four days later, prophylactic dissection of the left inguinal nodes was done. The nodes were not involved metastatically. In November 1952, an intradermal nevus was excised from the left scapular region, and a junctional nevus was removed from the right scapular zone. Dilation and curettage were performed in July 1953, for an incomplete abortion. No further trouble ensued until 1958, at which time cholecystectomy was done for gallstones. This operation was done at the clinic; the surgical notes, dated December 5, 1958, mentioned some enlargement of the left external iliac nodes, but the ovaries were described as being normal.

Examination in August 1959, disclosed a 7-mm., dark, raised, rounded cutaneous lesion on the posterior aspect of the left scapular region and two palpably enlarged lymph nodes in the left supraclavicular zone. Pelvic examination delineated a round mass in the cul-de-sac, separate from the uterus, and a flat firm mass along the left pelvic wall. These masses were ascertained to be extrarectal on proctoscopy.

The results of urinalysis and the values for hemoglobin, leukocytes, the differential count, platelets, prothrombin time, coagulation time, and the erythrocytic sedimentation rate were normal. Roentgenograms of the thorax revealed linear fibrosis at the right base, with elevation of the right hemidiaphragm. The pelvic findings and the past history appeared to be consistent with the diagnosis of a pelvic malignant tumor.

The abdomen was explored through a primary lower midline incision. Both ovaries were the seat of large, dark, nodular, solid tumors. Bilateral salpingo-oöphorectomy was performed. There were no peritoneal implants, and the liver, spleen, and kidneys were normal to palpation. Bilateral involvement of the iliac and aortic nodes up to the level of the pancreas made dissection of the nodes inadvisable. It was thought that the enlarged supraclavicular nodes likewise represented metastasis. Excisional biopsy of the cutaneous lesion near the left scapula was done.

The patient subsequently received nitrogen mustard therapy. She died from complications of the primary disease in November 1959. Necropsy revealed metastatic melanoma of the meninges, skull, liver, spleen, lungs, bones, and lymph nodes. Myocardial hemorrhage and infarcts in the basal nuclei of the brain were present.

Pathologic Features

Both ovaries were replaced grossly by nodules of tumor (Fig. 1*a*). The right ovary weighed 30 gm. and measured 4 by 3 by 3 cm.; the left one weighed 75 gm. and measured 8 by 5 by 5 cm. The tumors were encapsulated, nodular and solid, with colors ranging from dark gray to sooty black. The cut surfaces disclosed that the growths were solid throughout and were transected by fibrous bands, resulting in compartmentation of the tumors into aggregates of nodules of varying sizes (Fig. 1*b*). The fallopian tubes were normal in gross appearance. The lesion near the left scapula consisted of a dark subcutaneous nodule 1 cm. in diameter suggestive of metastatic malignant melanoma.

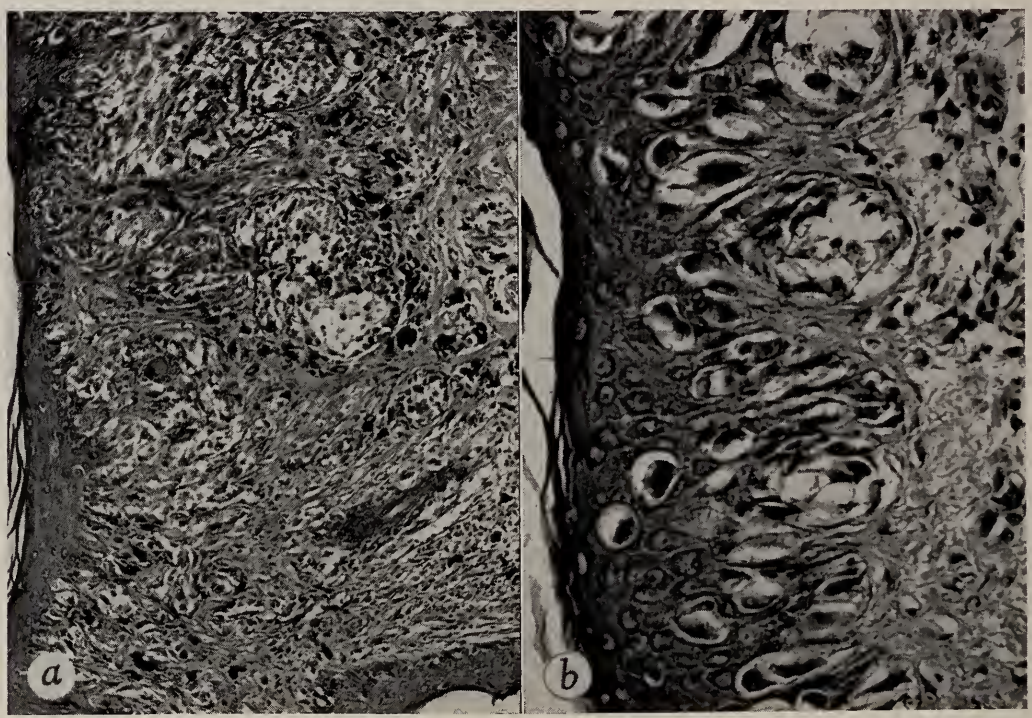

Fig. 2. Primary cutaneous tumor. *a*. Note pigmentation and deep invasion of lymphatic spaces (hematoxylin and eosin; x100). *b*. Growing edge of primary tumor, showing giant malignant melanoblasts in "junctional" position (hematoxylin and eosin; x300).

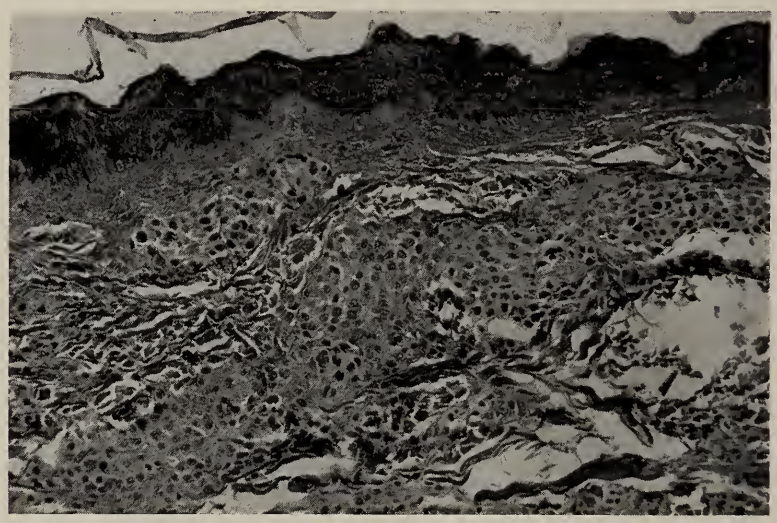

Fig. 3. Metastatic cutaneous lesion near scapula, showing characteristic subepithelial position of clusters of metastatic melanomatous cells (hematoxylin and eosin; x100).

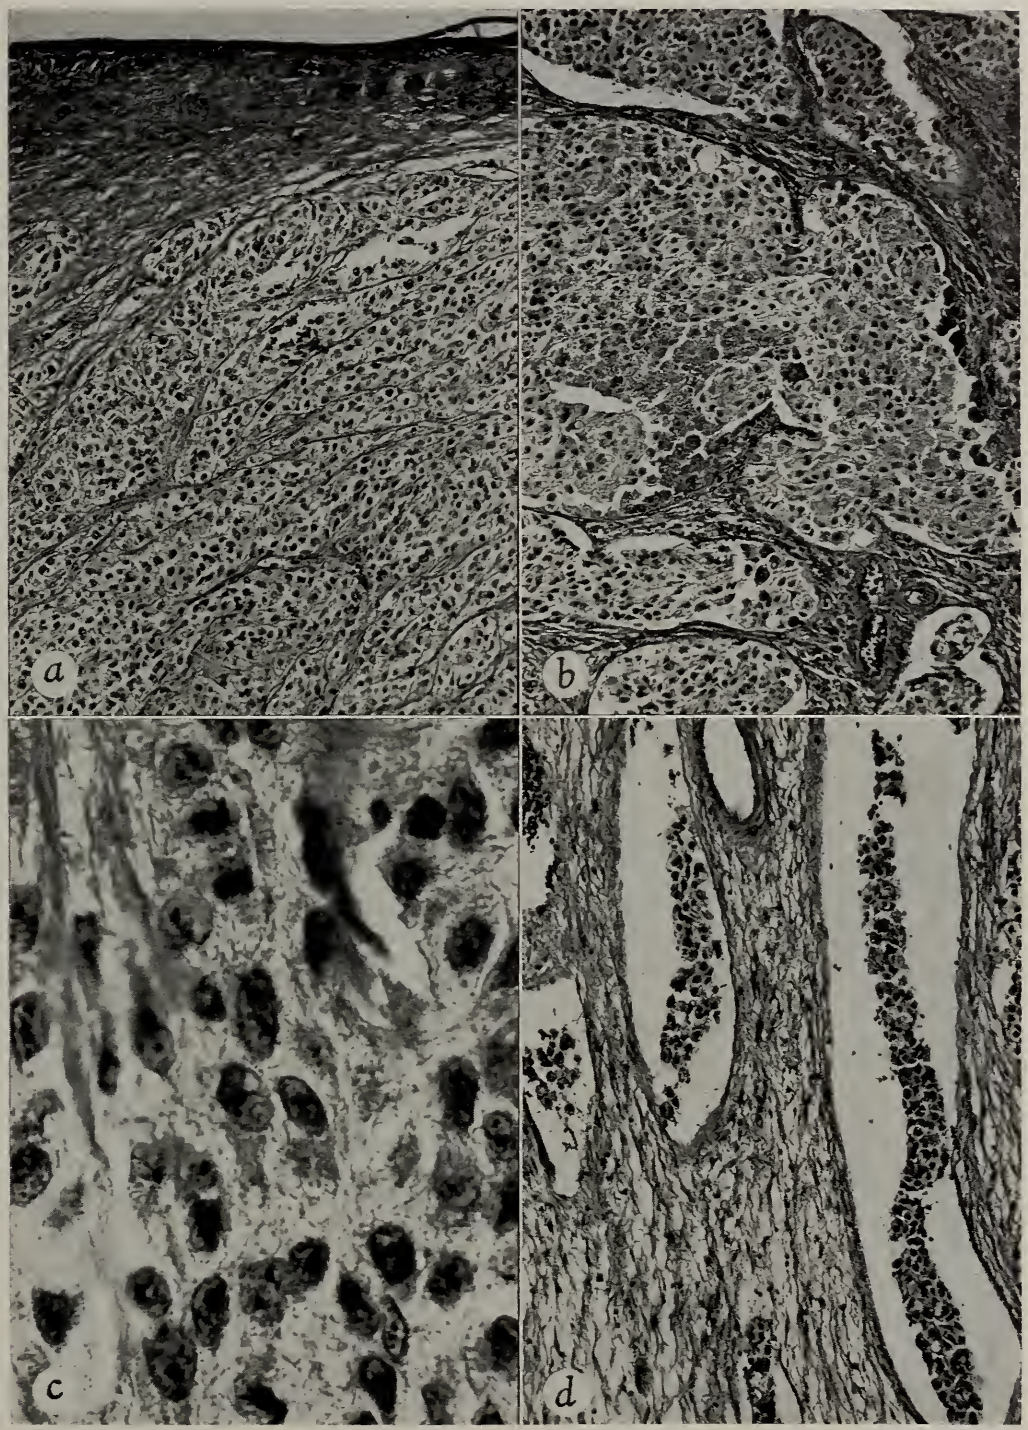

Fig. 4. *a*. Right ovary, showing masses of malignant melanoma growing beneath uninvolved rind of "capsular" ovarian cortex (hematoxylin and eosin; x100). *b*. Sheets and alveolar clusters of large granular tumor cells lend an epithelial flavor to nodule from left ovary (hematoxylin and eosin; x100). *c*. Right ovary, showing zone in which tumor cells have assumed spindle shapes. A mitotic figure appears in the upper part (hematoxylin and eosin; x600). *d*. Both ovarian hili exhibited lymphatic plugging by tumor cells to suggest lymphogenous spread to ovaries (hematoxylin and eosin; x100).

Sections of the primary tumor that had been removed in 1952 showed a typical malignant melanoma, with anaplastic melanoblasts present superficially in a junctional position and involving lymphatic structures more deeply (Fig. 2). A large amount of melanin was present. The metastatic nodule from the scapular zone contained clusters of malignant melanoblasts beneath the epidermis, as is typical for metastatic cutaneous lesions of this type (Fig. 3).

Except for an identifiable uninvolved rind of capsular cortex (Fig. 4*a*), the ovaries were replaced completely by large, granular, melanin-containing, epithelial-like tumor cells arranged for the most part in sheets and alveolar clusters (Fig. 4*b*). Occasional spindling was noted, which is a fairly common variation from the usual polygonal form of melanoma cells (Fig. 4*c*). Perhaps the most arresting feature in both ovaries was the plugging of almost all of the ovarian hilar lymphatic vessels with masses of tumor cells (Fig. 4*d*), a feature that strongly suggested a lymphatic pathway for involvement of the ovaries in this case.

Comment

The clinical features of interest in this case included the long latent period between the removal of the primary tumor and the appearance of the metastatic ovarian lesions. Although the pelvic nodes were enlarged at the time of cholecystectomy, in 1958, direct palpation of the ovaries at that time did not disclose any gross involvement. It is rather paradoxic that malignant melanomas, which are considered to be among the most aggressive of all malignant neoplasms, frequently give rise to metastatic lesions that may remain clinically quiescent for ten years or more.

Pathologically, it is intriguing that the ovary, which so frequently plays host to lesions of a lower order of malignancy, so rarely should be the site of metastatic malignant melanoma. Yet in this case, the liver, kidneys, and other visceral "favored" sites of metastasis apparently were bypassed for the selection of both ovaries for establishment of the principal secondary sites of spread.

With respect to the pathogenesis of the ovarian involvement, the absence of ascitic fluid, the absence of tumor cells in the superficial zones of the ovarian cortex, and the lack of involvement of ovarian hilar blood vessels were unusual features. Retrograde lymphatic permeation apparently was the method by which the tumor cells reached their ovarian destination in this case. The surgical verification of extensive nodal involvement is pertinent in this regard. Eventual spillage into the blood vascular system, probably via the thoracic duct, was indicated by the presence of the subscapular tumor, whose existence could not well be explained except on the basis of dissemination through the pulmonary vascular filter.

The presence of such neoplasms practically always implies a fatal outcome, the average postoperative survival in two large series of metastatic ovarian tumors being 4 months[8] and 11.1 months,[1] respectively. When encountered at laparotomy, these ovarian metastatic tumors, along with the tubes, should be removed to prevent such complications as twisting of the pedicle and ascites. A short period of comfort may be expected to ensue.

Summary

Although metastatic ovarian neoplasms are relatively frequent, metastatic malignant ovarian melanoma is exceedingly rare. A case has been reported in which the primary lesion was excised radically from the calf of the left leg seven years before the appearance of large solid metastatic tumors in both ovaries and in the skin near the left scapula. The patient lived for five months after the pelvic operation.

DIAGNOSTIC CRITERIA FOR RHEUMATOID ARTHRITIS

In 1956, a committee* of the American Rheumatism Association was appointed to formulate criteria for inclusion of a given case as rheumatoid arthritis in any study of the disease. This was thought to be necessary since an etiological classification is impossible at the present time; there is a lack of specific therapy which might serve as a basis for classification, or "therapeutic test"—for instance, colchicine in gout; there is uncertainty of identification in early and mild cases; atypical instances occur which later develop classical symptoms; there is a multiplicity of systemic diseases in which there are joint symptoms; and there is need of a common base line for comparing series of cases reported from diverse sources as to incidence, prevalence, course, treatment, and other features. There is also need for a category to include doubtful cases to be followed, but not to be included in present reports of series of rheumatoid arthritis. It is the plan of the committee to review the criteria every two or three years. The last review was in 1958.

The criteria were selected after consulting the Pittsburgh epidemiological study†, and questionnaires completed by physicians in the United States and Canada interested in arthritis. Signs and symptoms of rheumatoid arthritis which are nonspecific were discarded, such as fatigue, weight loss, anorexia, fever, lymphadenopathy, anemia, leukocytosis, leukopenia. Also discarded were signs of musculo-skeletal inflammation, such as tenosynovitis, muscle atrophy, skin atrophy. Conditions found to be of little value in diagnosis were eliminated, such as vasomotor symptoms, pericarditis, myocarditis, pleurisy, and reversed A/G ratio.

The following, in outline form, is the classification determined, together with a list of diseases, the presence of which was regarded as excluding such a case from a study of rheumatoid arthritis.

I. Rheumatoid Arthritis

A. *Classical Rheumatoid Arthritis.*—This diagnosis requires seven of the following criteria; duration of criteria (1) through (5) must be continuous for at least six weeks.

(1) Morning stiffness.

(2) Pain on motion or tenderness in at least one joint (observed by a physician).

(3) Swelling, soft tissue thickening or fluid (not just bony overgrowth), in at least one joint, observed by a physician.

(4) Swelling (observed by a physician) of at least one other joint. Any interval free of joint symptoms between the two involvements may not be more than three months.

(5) Symmetrical joint swelling (observed by a physician) with simultaneous involvement of the same joint on both sides of the body. (Bilateral involvement of mid-phalangeal, metacarpophalangeal or metatarso-phalangeal joints is acceptable without absolute symmetry. Terminal phalangeal joint involvement will not satisfy this criterion.)

(6) Subcutaneous nodules, observed by a physician, over bony prominences, on extensor surfaces or in juxta-articular regions.

(7) X-ray changes typical of rheumatoid arthritis, which must include at least bony decalcification localized to, or greatest around the involved joints and not just degenerative changes. Degenerative changes do not exclude patient from the group of rheumatoid arthritis.

(8) Positive agglutination test—demonstration of the "rheumatoid factor" by any method which, in two laboratories, has been positive in not over 5 per cent of normal controls—or positive streptococcal agglutination test.

(9) Poor mucin precipitated from synovial fluid with shreds and cloudy solution. (Addition of acetic acid gives a fat clump in a clear fluid in normal synovial fluid.)

(10) Characteristic histologic changes in synovial membrane with three or more of the following: marked villous hypertrophy; proliferation of superficial synovial cells often with palisading; marked infiltration of chronic inflammatory cells (lymphocytes or plasma cells predominating) with tendency to form "lymphoid nodules"; deposition of compact fibrin, either on surface or interstitially; foci of cell necrosis.

(11) Characteristic histologic changes in nodules showing granulomatous foci with central zones of cell necrosis, surrounded by proliferated fixed cells, and peripheral fibrosis and chronic inflammatory cell infiltration, predominantly perivascular.

B. *Definite Rheumatoid Arthritis.*—Requires five of the above criteria: Criteria (1) through (5) should have duration of at least six weeks continuously.

C. *Probable Rheumatoid Arthritis.*—Requires three of above criteria; in at least one of criteria (1) through (5), continuous presence for at least six weeks.

D. *Possible Rheumatoid Arthritis.*—Two of the following and total duration of joint symptoms of at least three weeks: (1) morning stiffness, (2) tenderness or pain on motion (observed by physician), (3) history or observation of joint swelling, (4) subcutaneous nodules (observed by a physician), (5) elevated sedimentation or C-reactive protein, (6) iritis.

*The American Rheumatism Association committee is: Marian Ropes, M.D., chairman, Granville Bennett, M.D., Sidney Cobb, M.D., Ralph Jacox, M.D., and Ralph Jessar, M.D. Published in part in *The Bulletin* (ARA).

†Cobb, S., et al: J. Chronic Dis., 2:50, 1955 and 3:134, 1956.

II. Exclusions

1. High concentration of L-E cells (four or more in two smears prepared from heparinized blood incubated not over two hours) or typical rash of L-E.
2. Histological evidence of periarteritis, dermatomyositis, scleroderma, sarcoid, multiple myeloma, tuberculosis in joints or tubercle bacilli in joints, leukemia or lymphoma.
3. Gout
4. Specific infectious arthritis
5. Rheumatic fever
6. Reiter's syndrome
7. Shoulder hand syndrome
8. Hypertrophic pulmonary osteoarthropathy
9. Erythema nodosum
10. Alkaptonuria and ochronosis
11. Agammaglobulinemia
12. Neuroarthropathy

The criteria in the groups designated as *classical* and *definite* rheumatoid arthritis are rigid enough to be as sure as possible that all cases included are truly examples of rheumatoid arthritis. This is essential because patients in these categories will be used for study of disease, and as a basis for figures on prevalence, incidence, course, and therapy. However, they are not so strict that only cases of great severity or long duration should be included. Therefore, the duration was made fairly short—six weeks or more. This minimum duration usually excluded such illnesses as infectious arthritis, traumatic arthritis, and rheumatic fever. Also as small a number of affected joints were required as possible; only one at a time if other laboratory or clinical evidence was present.

It is important not to exclude a patient who has rheumatoid arthritis because he also has degenerative joint disease, an error that is commonly made. Uncomplicated degenerative joint disease is excluded by the rigid criteria stated for rheumatoid arthritis of soft tissue swelling and symmetry, *not limited to the terminal phalangeal joints,* nodules, and characteristic laboratory findings.

With regard to the exclusions, most are apparent, but it is well to point out that a rheumatoid arthritis patient may be thought to have another generalized connective tissue disease, or gout, or rheumatic fever. It is wise not to include such a patient in a study of rheumatoid arthritis, but to classify him separately and compare as desired. But patients with rheumatoid spondylitis, psoriasis, ulcerative colitis, or juvenile rheumatoid arthritis (onset before age twelve) are to be included in rheumatoid arthritis groups if they satisfy the criteria.

MARIAN TYNDALL, M.D.

A PROFESSION ON THE HORIZON

The traditional professions of law, medicine, education and several others are marked by definable characteristics common to the professions. Thus, members of these groups have (1) successfully completed a formal course of study prior to engaging in "clinical" practice; (2) mastered a specific body of knowledge in addition to technical skills; (3) received approval by members of the professions; (4) been licensed by the state in which they chose to practice; and (5) dedicated their careers to service without regard for personal aggrandizement. It is this final requisite which is the single most important mark of a professional person. It is this which raises him above the skilled technician or the learned craftsman. Also, it is this trait which is manifestly lacking in the non-professional person.

Within the framework of our definition, there are relatively few, if any, men today who might be classified as professional police officers. There does not yet exist any group within the field of law enforcement which has established or which can enforce professional ethical standards. Likewise, there are no established certification procedures beyond the local selection screening processes.

Despite these apparent shortcomings in law enforcement, there is an increasing number of men who may be considered as professional police officers. The completion of a pre-service educational program, mastery of the literature of law enforcement and a clear dedication to public service are traits common to countless men today routinely engaged in the protection of society and in the enforcement of laws.

The test of professionalization is primarily applied at the level of selection-for-appointment. It is here that the unfit, the incompetent and the unstable must be eliminated. It is here that the most rigid requirements must be satisfied.

Experience and wisdom dictate that pre-employment residence requirements be abolished, that intelligence levels above average be required, that psychiatric examinations be mandatory, that candidates be free of criminal experience and associates, and that educational standards be met. That

---

This is another in the series of editorials from The Law-Medicine Center of Western Reserve University, Cleveland, Ohio. The author is an investigator with the Cuyahoga County Coroner's Office and a Clinical Instructor in Criminology at Western Reserve University.

these simple and inexpensive selection standards are not universally applied attests to the strength of the political ties which bind the administrator's hands. In each individual case, it is difficult to determine precisely whether the inadequate selection procedures are erected as monuments to ignorance or to selfish political control. In either case, it is a serious indictment of those politicians who first established and who have since perpetuated selection standards that only 10 per cent of American cities employ the psychiatric examination, that some police agencies fail to fingerprint their candidates, and that educational requirements are forbidden by state statute in some areas.

The existence of these negative conditions implies far more that mere cultural lag whereby a social institution lags behind accepted change for a number of years. These conditions indicate that many persons (administrators and politicians alike) are satisfied with the inferior selection standards as they presently exist in many communities. It may be said that the vocal minority who insist upon tight local control over police selection are the same few who benefit so greatly from that control. For example, the mayor who can tear up traffic tickets for his friends, who can have his inebriated companions chauffered home in police cars, and who can reward loyal political chronies with police positions would certainly favor standards far below those recognized as being vital necessities of professional law enforcement. No other requirement is so directly related to politics as the minimum age requirement of the great bulk of departments. Twenty-one years of age is the minimum age for appointment. This requirement is tied directly to the voting age in this country. Rationalizations for this practice in the name of maturity and stability are hollow phrases in view of the military accomplishments of the so-called boys under twenty-one. Law enforcement is one of the few endeavors which refuses to compete in the labor market for the greatest number of men. Thus, police departments frequently are forced to select from those who have spent three or four years out of high school in other jobs or who have remained unemployed. Immediate steps must be taken to find non-crucial positions for high school graduates, positions which can serve as training and as a springboard into regular duty status.

Professionalization to many persons is interpreted to mean a salary approximating that of one of the traditional professions. Many persons become entangled in the circular argument which says that in order to attract good men you must first offer good wages while, on the other hand, good wages should be offered only to good men. This chicken vs. the egg discussion has served to impede rather than hasten professionalization for those police officers who insist that salaries alone will bring about the immediate elevation of standards.

Regardless of which comes first, the salaries or the standards, one thing is clear—professionalization of police service must come from within the ranks of law enforcement. The insistence upon the highest standards for appointment, the demand for pre-service training and the determined refusal to make and share the bed of the local politicians are prerequisites for professional service—prerequisites which must be fostered and developed by police officials.

Throughout any discussion of professionalization must be carried the important thought that every police officer will not become a police chief or an administrator. The majority of men will remain as patrol due to the narrowing pyramid of supervisory positions. Thus, selection procedures and professional standards must be realistic. They must recognize that varying levels of competence and intelligence are needed. But, agreement can be had on the fact that the minimum standards should be high enough to provide communities with intelligent, stable, forthright individuals who can meet the challenge of our complex social and legal system.

Despite the general lack of adequate selection and training procedures throughout this country, many persons are pleasantly surprised to find such a large number of competent and dedicated persons in police work today. Modern police work today is as challenging an endeavor as any to be found. Lacking strict standards on a national scale, a number of departments have grown into truly professional agencies. Certainly, in every department in this nation, there are a number of men who must be labelled as dedicated, for few police salaries could attract and retain persons of their caliber. These are the men who value and cherish the dream of professional status and who have dedicated their own careers as examples of what can be accomplished—and what should be demanded.

George W. O'Conor

President's Letter

WE JOIN THE FIGHT AGAINST FOOD FADDISM

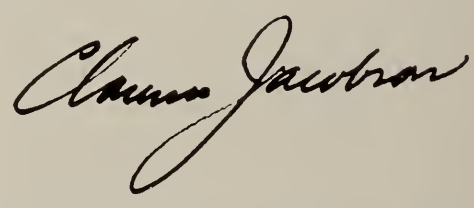
We have been told that Americans annually spend nearly a half-billion dollars on food supplements in pill, powder, capsule or compound form.

Pseudo-nutrition experts are doing an effective job of selling Americans on the idea that their product will provide a shortcut to health.

Common variations on the necessity for food supplement theme include the following: all diseases may be due to diet; soil depletion causes malnutrition; modern food processing and cooking methods reduce food values; and, that "tired feeling" is always due to a dietary deficiency.

Thankfully, most of these dietary supplements are harmless to persons in good health.

How often have we not told our patients that a well-balanced daily diet includes all the nutritional requirements to maintain good health at a fraction of the cost of food supplements. Truly, the educational program of the modern medicine man, his lecture hall and door-to-door diagnostic techniques have made their inroads.



Forceful allies of the medical profession in the fight against food faddism include the U. S. Food and Drug Administration and the Federal Trades Commission. The FDA inspects and assures the purity, wholesomeness and safety of foods sold in interstate commerce; while the FTC places checks on false advertising claims which have been found to be untrue or misleading. In addition, the AMA has prepared an effective Food Faddism Campaign Kit. This is available to county medical societies and individual members from our State Office.

The kit includes program ideas, a sample speech, and samples of public health education literature on food faddism available for distribution to the public. Also included is a descriptive folder of the AMA food faddism film, "The Medicine Man."

At the May 23, 1960, meeting of the Public Health Education Committee, Minnesota physicians were assured of the services of the members of the Minnesota Dietetic Association in a state-wide education program against food faddism. Dietetic Association representatives at that meeting informed members of the Public Health Education Committee that a statewide program to combat food fads and food misinformation has been drawn up by that organization and dietitians throughout the state have been contacted and urged to support the program.

The program, sponsored by the Minnesota Dietetic Association with the support of the Minnesota State Medical Association and the co-operation of the Woman's Auxiliary, will go into operation on September 1, 1960. The program format will include showing of "The Medicine Man." Plans are to have a physician and a dietitian present to introduce the film, explain its purpose and answer dietary questions.

The nutritional quack has spared nothing to tell his story to the public. Can we afford to do less?

President, Minnesota State Medical Association

Medical Economics

Edited by the
Committee on Medical Economics,
Minnesota State Medical Association
George Earl, M.D., Chairman

"THIS IS THE ELEVENTH HOUR," AMA AUDIENCE TOLD

"There seems to be a widespread dilusion existing today that money coming from Washington, for some strange reason, doesn't cost anybody anything," according to Mr. Chester Lauck, Executive Assistant of the Continental Oil Company of Houston, Texas.

Mr. Lauck, who spoke to AMA Delegates, members of the Board of Trustees and guests at a breakfast sponsored by the Arkansas Medical Society held in conjunction with the 109th Annual Meeting of the American Medical Association, told the group that America is riding the crest of a wave of prosperity never before dreamed of on this earth.

He pointed out that in spite of this prosperity, we suddenly find ourselves 295 billion dollars in debt. We owe more money in this country than all the other nations on earth put together. WHY? Simply because we have been spending more than our income. We have become involved in a deficit spending program for a number of years because people will not realize that the government does not have a stockpile of funds back in Washington which they can dispense or distribute at will.

"Mr. Khrushchev has declared that the Soviet Union no longer expects to defeat the United States on the battlefield of the military but rather has elected to destroy us on the battlefield of economy. They are aiming directly at the strength and stability of our American dollar. It is their hope that we will spend ourselves into bankruptcy and if we continue our deficit spending program, we are aiding and abetting their cause.

"Washington is not entirely at fault. Let's put the blame where it belongs—on ourselves. We have not assumed our responsibility of citizenship. WE ASKED FOR IT. Every project we undertake—whether it is for a rural community, a village, city, county, or state, or whether the project be an overpass, underpass, bridge, airport or even urban renewal—the first question usually asked is 'How much government aid can we get?' It is generally asked without any regard or consideration as to where the funds might be coming from."

The speaker expressed the belief that we have forgotten how to do things for ourselves. We forgot that with grants-in-aid come government controls, and with government controls we cannot embrace the free and competitive enterprise system—the system that brought about this prosperity and made America so outstandingly great.

Someone recently said, "We have been living mighty high on the hog, but it 'ain't' our hog—it belongs to our children." Are we just going to drop this $295,000,000,000 debt in their laps and ask them to scramble out of it the best way they can? Our children and future generations are entitled to inherit this republic as we found it—with freedom and opportunity, intact and unmortgaged.

"Some economists say we are beyond the point of no return. This is hard to believe. We must realize, however, that this is THE ELEVENTH HOUR. We must realize the direction toward which we are drifting and do something about it *NOW*. We have got to concern ourselves with government matters—to get into politics. Too many for too long have been saying, 'I don't know anything about politics; I leave that up to the politicians.' The result is that a handful of people have been running this country. And our $295,000,000,000 debt, socialistic welfare programs, and the present threat against our free and competitive enterprise system indicates quite clearly HOW they have been running it."

Mr. Lauck emphasized that we must begin at the grass roots. In order to accomplish this, he advocated we must attend our local precinct meetings, finding out what candidates for office stand for—not whether they are Democrats or Republicans, but what kind of Democrats, what kind of Republicans. He told the group that we have too many Democratic Congressmen and too many Republican Congressmen in Washington and not enough United States Congressmen.

"It is not too late to put the love of our country above partisanship interests by selecting conserva-

tive candidates for office and then supporting them with all our strength and influence. In this way, and only in this way, can we hope to preserve our Constitution and the American way of life.

"We can and must select men for office who will think of the next generation rather than the next election."

Mr. Lauck stated that now we must prove that we are of the same sturdy stock as were our forefathers by assuming the responsibility of preserving the heritage they willed us. THIS IS THE ELEVENTH HOUR!

The members of the American Medical Association, as individuals, must stand up and be counted and exercise the influence which their position in their community places them, and the American Medical Association must stand as a body to defend our free enterprise system and to ward off the threat of socialized medicine.

There are two things with which we need to be concerned. We need roots to hold us firm and we need sky to hold us up, and in between, a living process. Because, out of our beliefs we perform deeds, and out of our deeds we form habits, and from our habits grow our character, and ON OUR CHARACTER WE BUILD OUR DESTINATION, concluded Mr. Lauck.

REPRESENTATIVE CURTIS RAPS FEDERAL GOVERNMENT INVASION OF MEDICINE

Representative Thomas B. Curtis, a key figure in the House Ways and Means Committee, was the guest speaker at the dinner for Delegates and their wives held in conjunction with the 107th Annual Meeting of the Minnesota State Medical Association.

The ranking Republican on the House Ways and Means Committee, Representative Curtis of Missouri, characterized the main supporters of Forand-type legislation as leaders of the AFL-CIO's Committee on Political Education (COPE) —a body he said represents not the views of organized labor but of the left-wing Americans for Democratic Action, ADA.

COPE, he said, has consistently smeared the AMA as an organization consistently against things, ultra-conservative and always motivated by ulterior motives. "It's been a clever smear job," he said.

Supporters of the Forand Bill almost won the case, he said, before it came before Congress, by phrasing its argument with an innuendo that the government now does nothing in the field of health care for the aged. There is plenty of help coming from the federal government now, he said.

Phony Statistics

The congressman cited "phony statistics" used by supporters of the bill, such as "51 per cent of those over sixty-five have an income of $1,000 per year or less." That figure, broken down into what he called meaningful figures reads that 34 per cent of the men and 71 per cent of the women over sixty-five are in that income group. This argument loses some of its urgency, he said, because men are generally the breadwinners.

Other examples include the statement that costs of health are greater after sixty-five than before. This is true only in the case of medical costs. Food, clothing and all other living costs are decreased, he said.

The Forand Bill, he charged, doesn't help those who really need assistance. Widows of farmers, businessmen and other members of the economic community not covered at the time of death, will not be eligible for help.

Also not covered is the victim of the "catastrophic illness"—the cost of which could wipe out savings of a lifetime.

Such a program, he said, would necessarily result in socialized medicine. The government, he said, rather than the patient, would be the one which would ultimately have to choose the physician.

Blue Cross and similar health insurance plans, he said, now cover nearly half of the people in America. The figure is expected to jump this year. Insurance is now available for those over sixty-five at premiums which range from $55 to $140 a year, he said.

He also cited AMA testimony at hearings earlier this year in which doctors claimed there is "no one in the United States, regardless of his financial condition, who can't get adequate medical care."

Help Pay Premiums

Representative Curtis said he is in favor of looking into legislation which would help pay premiums for health insurance by private companies; extending coverage to pay for nursing home care and home care, which would be less expensive. Above all, he said, more public hearings should be held to determine the best legislation possible.

AUBREY GATES URGES GREATER MD POLITICAL ACTION

The Director of Field Services for the American Medical Association, Mr. Aubrey Gates, who preceded Representative Curtis on the speaker's platform at the delegates dinner, urged doctors themselves to take the lead in fighting socialized medicine by taking a more active role in politics. He reminded his dinner audience that this is an election year.

Mr. Gates pointed out that both doctors and their wives must get into the political action field and join with other conservatives to forestall legislation which would be harmful to the medical profession.

"How many of you know your congressman," he asked, "or your sheriff, county clerk, or county political party chairman?"

Congressmen, Gates said, often "complain that doctors only contact them when they are in trouble." The medical profession can get a valuable ally by making use of the contacts they have.

"We can't work this thing alone," he said, and called on doctors to help elect "good candidates" by talking to their 2,000,000 patients and seeking the alliance of other conservatives in the business and professional community.

CALIFORNIA GOVERNOR PROPOSES ELIMINATION OF BRAND NAME DRUG PAYMENTS

A new state policy to save money spent for brand name drugs has been proposed by California's Governor Pat Brown. The California Chief Executive has suggested that the California State Board of Social Welfare adopt a new policy which would eliminate payment for brand name drugs for public assistance recipients when equally effective non-brand name drugs are less expensive.

He expresses belief that considerable savings could be made in the $10 million to $12 million spent yearly on drugs under various state aid programs. These include aid to the aged, the blind, the disabled and needy children.

The Governor's request was based on a study by the State Public Health Department which revealed prices vary greatly depending on whether a drug is dispensed under a brand or generic name. He said competent medical advice is available to help the Social Welfare Board determine the drugs to which the new policy could apply.

NEW AMA PRESIDENT CITES CHALLENGE

Medicine faces its greatest challenge in the next decade, said Dr. E. Vincent Askey, Los Angeles, who was installed as the 114th President of the American Medical Association. He called the next ten years "the decisive decade."

Threat Cited

Doctor Askey cited the continuing threat of government intervention into medical practice at a time when the nation is enjoying the best health in its history. He pointed out that medicine moved quickly, applying rapidly developing medical tools and techniques in the "fifties" because it was free to move, unhampered by government restrictions.

"It is ironic," said Doctor Askey, "that at the very moment our capacity for individualized treatment is heralding a revolution in medical care, the pressures mount heavier to force us into adoption of assembly line methods."

Several hundred physicians and guests heard Doctor Askey present his inaugural address and John S. Millis, Ph.D., President of Western Reserve University, Cleveland, Ohio, who spoke on "Responsibility in a Changing World."

Medal Given Doctor Orr

The past president's medal was presented to retiring President Louis M. Orr, M.D., Orlando, Florida, by Leonard W. Larson, M.D., Bismarck, North Dakota, Chairman of the AMA Board of Trustees and President-Elect. Doctor Larson hailed Doctor Orr for the "vitality and dedication" with which he led the medical profession in one of its more troubled times.

In accepting the medal, Doctor Orr said the price of progress can only be continuing observance of those standards in medical affairs which lead moral conduct, community activities and political endeavors toward the goal of ever-increasing medical advances.

The 1960 recipient of the American Medical Association's Distinguished Service Award also was honored at the inaugural. Dr. Charles A. Doan, Dean of the Ohio State University College of Medicine and Director of the Health Center in Columbus, was presented the award for his outstanding work in the field of hematology.

MD Cannot Be Cog

Throughout the evening the point repeatedly was made that no doctor can function effectively as a cog in a governmental machine.

"A cog must turn as the wheel turns—must mesh, obedient to the machine of which it is a subordinate part. A cog can exercise no judgment, demonstrate no skill, deviate to no appreciable degree from its prescribed function," the new AMA president concluded. "Good doctors make bad cogs; good cogs become bad doctors."

To meet the challenge of government intervention, Doctor Askey said, the medical profession must be more active in community affairs. In addition to his continued postgraduate educational efforts and dedicated service to his patients, each doctor must make his viewpoint known. He must speak out in behalf of his profession in health matters.

JOBS FOR AGED, DEFEAT OF GOVERNMENT MEDICINE URGED BY RETIRING AMA PRESIDENT

In his farewell address, Dr. Louis M. Orr, retiring President of the American Medical Association, urged physicians to remain vigilant in efforts to defeat old or new Forand-type legislation embodying features of compulsion in providing for the health needs of the aged or other selected segments of the population.

Pointing out that medicine favors "the best kind of medical care for the aged" achieved through voluntary, competitive methods, Doctor Orr recommended that the House go on record favoring:

** More jobs for the aged.

** Voluntary retirement.

** A campaign against discrimination because of age, whether it be forty or sixty-five.

Lauds Aged Bill

Doctor Orr also said the AMA believes the House Ways and Means Committee acted wisely in approving a new Title XVI to the Social Security Act initiating a federal-state, grant-in-aid program to help states assist the near-needy aged who cannot meet their medical expenses.

AMA has committed itself to leadership in studying and answering questions related to the cost of medical care, Doctor Orr also said, by establishing a Commission on Medical Care Costs.

Doctor Orr, who serves as chairman of the Commission, said medicine long ago pledged itself to "provide the best possible care at the least possible cost" to all people. He said it is imperative that physicians adhere to the principle of charging reasonable fees for professional services rendered. Otherwise, doctors pave the way for outside intervention and control of medicine.

SURVEY SHOWS WHY PATIENTS DISREGARD PRESCRIPTIONS

Patients disregard at least 14 per cent of all prescriptions, according to a survey by Lakeside Laboratory.

Results of the survey showed that of every 100 prescriptions written, sixty-nine were filled, seventeen were not filled because the product was unavailable at the drug store and fourteen were not filled because the patients totally disregarded them.

Reasons given by the 14 per cent of the patients who failed to have the prescriptions filled were as follows:

The patients "felt better the very next morning." "Couldn't get the prescription filled, the drug store was closed." The patient "recognized the name of the drug, it wasn't helpful to me before."

JUDGE CRITICIZES ATTORNEYS WHO FILE MALPRACTICE CASES WITHOUT SUBSTANTIAL GROUNDS

On March 17, 1960, Judge Felix Forte, of the Superior Civil Court, Lawrence, Massachusetts, severely criticized attorneys who present malpractice cases without having substantial grounds for such action, as he directed verdicts in three malpractice actions for the defendant physicians.

In commenting to the jury, Judge Forte said, "If every time an operation goes wrong a doctor is going to be sued and goes through the trouble and expense these doctors have gone through, how many doctors are going to be willing to take those chances?"

Public Health

METROPOLITAN AND SUBURBAN WATER PROBLEMS

Studies during the past year have disclosed that much of the ground water supplying individual wells in built-up areas, where septic tanks and soil absorption systems have been used for disposal of sewage, shows the effect of the sewage through the presence of chemicals and bacteria of sewage origin. In the metropolitan area, where some 375,000 persons are dependent on such facilities. surveys have been made of thirty-three communities with some 55,000 wells. Results have ranged from no evidence of sewage in the wells of one small community to 100 per cent of the wells affected in a half-dozen others. The overall results in the communities surveyed show that 50 per cent of the wells tested were contaminated by sewage as evidenced by the presence of detergents or elevated nitrates.

The likelihood and extent of this condition are dependent upon several factors, such as, population density, well depth, and type of soil. Deeper wells have been less affected than shallow ones and wells in areas of dense clay are less likely to be contaminated than those in sand, gravel or broken rock.

Although there have been no cases of illness reported as being caused by this situation, the presence of sewage in drinking water must be regarded as a hazard. The greatest need, of course, is provision of water from a safe source, usually on a community or area basis since it is more economical to build one safe water supply to serve a large number of users than for each to provide his own. In addition it is necessary to plan for proper sewage collection and treatment of sewage to avoid the ultimate contamination of the deeper water sources.

Surveys made in a half dozen out-state communities have shown that the contamination of ground water by septic tank effluents is not limited to the metropolitan suburbs. The results of all of the studies confirm the contention of health officials that while individual wells and septic tanks can give satisfactory service in isolated situations they are not suitable for use in densely populated areas.

The Federal Housing Administration has set limits on the amount of sewage chemicals that it will accept in the water for properties for which it will insure mortgages. This and the general concern over water quality has stimulated several of the metropolitan suburbs to plan for public water systems. Some of them propose to contract for water from one of the major cities, while others prefer to construct their own wells. With a limit to the amount of water that can be drawn from the ground, it appears that in time it will be necessary for more and more water to be taken from the Mississippi River. Here again there is a limit to the amount of water that is available during periods of low flow.

In 1961 legislative session, bills will be introduced on several subjects relating to this situation. Among these will be bills for:

1. Providing an expanded sewage disposal authority for the Twin City metropolitan area.
2. Authorizing the creation of sanitary districts to solve sewage disposal problems not limited to a single community.
3. Simplifying the procedure for a municipality to provide a public water supply.
4. Providing for augmentation of low flows in the Mississippi River by regulating the storage and use of water in the headwater reservoirs.

A bill is also likely to be introduced to authorize creation of a single water authority for the Twin City area, probably as a part of a multi-purpose authority to deal with water supply, sewage disposal and other problems common to the metropolitan area. While a central water authority is undoubtedly desirable for the future, in view of the need for regulating withdrawal of water from the various limited sources, it is not essential for the solution of present water problems of the suburbs, each of which can provide its own supply. Inclusion of this item could make difficult the enactment of the vitally needed legislation for creation of an enlarged sewage disposal authority.

Civil Defense News

CARL WALDRON, M.D., D.D.S., *Chairman, Civil Defense and Disaster Committee, Minnesota State Medical Association*

M. D. TYSON, *Civil Defense Co-ordinator, Minnesota State Department of Health*

COUNCIL CONFERENCE

The Ninth U. S. Civil Defense Council Conference, Medical-Health Section, will be held September 21-22, 1960, at the Leamington Hotel in Minneapolis, Minnesota.

The program for the two-day event is as follows:

Wednesday—September 21, 1960

A.M.

8:00 Registration
9:00 Call to Order—CARROLL HUNGATE, M.D.
9:10 The Chemical Warfare Threat—DR. CARL R. BREWER
9:50 The Biological Warfare Threat—LEROY FOTHERGILL, M.D.
10:30 Coffee Break
10:45 Civilian Medical Problems—COL. DAN CROZIER
11:25 What to remember—What has been done and what is still to be done about Chemical and Biological Warfare—CHARLES STEELE, M.D.
12:00 Combined Lunch—The Hall of States
Address: The HON. WALTER H. JUDD, U. S. Congressman from Minn.
Emergency Health Services

P.M.

2:00 Introduction—CARROLL P. HUNGATE, M.D.
2:15 Emergency Health Service Concept—C. J. WAGNER, M.D.
2:35 Community Emergency Health Program—GEORGE MOORE, M.D.
2:55 Health Manpower Management—ROBERT L. SMITH, M.D.
3:15 Health Mobilization Training—MR. JERROLD M. MICHAEL
3:35 Health Resources Management—MR. ARNOLD H. DODGE
3:55 Chemical, Biological & Radiological Defense (Non-military) MR. CHARLES H. HARP
4:15 Emergency Engineering and Sanitation—MR. CHARLES V. WRIGHT
4:35 St. Paul Day—Trip to St. Paul—Buffet Dinner —Ice Capades Show

Thursday—September 22, 1960

A.M.

9:00 Call to Order—EDWARD G. SHARP, M.D.
9:10 Chemical Warfare Defense Workshop—COL. GEORGE D. RICH
10:10 Biological Warfare Defense Workshop—DR. CHAS. PHILLIPS
11:10 Radiological Warfare Defense Workshop—MR. BENJAMIN KILLIAN
12:10 Medical-Health Luncheon—The Hall of States (Speaker to be announced)

P.M.

2:00 Call to Order—CARL WALDRON, M.D.
2:10 Civil Defense Emergency Hospital Workshop—MR. JERROLD M. MICHAEL
6:00 Social Hour—The Hall of States
7:00 Citation Banquet—The Hall of States

Outstanding personalities in the field of Civil Defense and Disaster preparedness will be honored.

Participants in the Conference are:

Carl R. Brewer, Ph.D., Chief, Research Division, U. S. Army Chemical Corps Research and Development Command, Washington, D. C.

Col. Dan Crozier, Office of the Surgeon General, U. S. Army, Washington, D. C.

Arnold H. Dodge, Chief Health Resources Branch, Division of Health Mobilization, P.H.S., Washington D. C.

Leroy D. Fothergill, M.D., Scientific Advisor, U. S. Army Biological Warfare Laboratories, Ft. Detrick, Maryland

Charles H. Harp, Chief, C.B.R. Defense Branch, Division of Health Mobilization, P.H.S., Washington, D. C.

Carroll P. Hungate, M.D., Chairman, Committee on Disaster Medical Care, American Medical Association, Member, Council on National Security A.M.A., Kansas City, Missouri

The Honorable Walter H. Judd, U. S. Congressman from Minnesota

Benjamin C. Killian, Physical Sciences Administrator, P.H.S., Region III, Charlottesville, Virginia

Mr. Jerrold M. Michael, Chief, Training Branch, Division of Health Mobilization, P.H.S., Washington, D. C.

George Moore, M.D., Program Director for Health Mobilization, P.H.S., Region III, Charlottesville, Virginia

Charles R. Phillips, Ph.D., Chief, Physical Defense Division, U. S. Army Biological Warfare Laboratories, Ft. Detrick, Maryland

Col. George D. Rich, Deputy Assistant Director for C.B.R. Defense, O.C.D.M., Battle Creek, Michigan

Edward G. Sharp, M.D., Medical-Health Liaison Representative, U. S. Civil Defense Council, Philadelphia, Pennsylvania

Robert L. Smith, M.D., Deputy Chief, Division of Health Mobilization, P.H.S., Washington, D. C.

Charles W. Steele, M.D., Member, Committee on Disaster Medical Care, A.M.A., and Liaison representative on Civil Defense, American Chemical Society, Chairman Committee on Disaster Medical Care, Maine Medical Association, Lewiston, Maine

Carruth J. Wagner, M.D., Chief, Division of Health Mobilization, P.H.S., Washington, D. C.

Carl Waldron, M.D., Co-Chairman, Medical-Health Committee, U. S. Civil Defense Council

Charles V. Wright, Assistant Chief, Division of Health Mobilization, P.H.S., Washington, D. C.

EXPOSE FOOD FADS THROUGH EDUCATION

One of the most disturbing problems in the field of nutrition and health is the speed with which food fads and food misinformation is spreading. Distorting facts into fads is a thriving business today and the twentieth century seems to have its own diversified brands of "cure-alls."

A vast amount of misinformation about diet is reaching the public by many channels. Through the media of mass communication—magazines, newspapers, radio, television—person-to-person, and even through libraries, the American people are being propagandized into trying this or that "quick cure." Never have so many false claims been made and never has so much false information been accepted by so many people.

There are several types of food fads. These include extravagant assertions for particular foods, emphasis on the use of "natural" rather than processed foods, self-prescribing of vitamin pills, the indiscriminate use of food supplements, the certainty of being poisoned from cooking in aluminum utensils, eating of "brain foods," and fads involving special reducing diets.

Age of "Modern Medicine Man"

An article in a recent issue of a well-known magazine reminds us that we are not as far away from the old-time medicine man of the last century as we would like to believe. According to the magazine story, "Adult feeding formulas" are conversation pieces at every gathering of informed persons.

The article suggests that it is possible to diet surely and painlessly through formula feeding and refers its readers to the labels on the products to find instructions for proper use.

Whatever the claim for these fabulous formulas, it is important to distrust any suggestion for self-medication and to remember that self-prescribing can be dangerous. Equally important is to have the advice and recommendation of a physician before going on any special diet. The "do-it-yourself" method may be a good way to install tile on the basement floor, but it is not the solution to weight reduction. Any person trying to reduce weight is taking a risk without guidance from a physician.

Food Quacks Lead Field

Speaking at the 1959 annual meeting of the American Dietetic Association, Wallace F. Janssen, Director, Division of Public Information, Food and Drug Administration, pointed out that more "quackery" is being practiced in regard to food and nutrition than in any other field. He suggests "the only effective means of combating this type of misinformation is education of the public." Education, continuing education, is the weapon which eventually will prove most effective in checking activities of the food faddist.

The American Medical Association is currently carrying out a campaign against food faddism and has produced an educational film on the subject entitled "The Medicine Man." The American Dietetic Association, the Nutrition Foundation, and the Food and Drug Administration, also, are presently active in the field of combating food misinformation.

United Education Program Announced

Three Minnesota organizations—The Minnesota State Medical Association with the assistance of the Woman's Auxiliary, the Minnesota Dietectic Association and the Minnesota Department of Health—have joined forces to set up an educational program of combating false and misleading propaganda about food. To present up-to-date fundamental facts and improve the scientific accuracy of information about

diet and nutrition, these organizations plan to hold a series of community meetings throughout the state beginning in September.

"For every food fallacy there is a food fact; for every 'rage,' 'vogue' or 'fad' diet there is a basic eating pattern built around the protective foods to provide adequate nutrition." To get this message from the American Dietetic Association, to the public and to provide accurate scientific information which everyone can understand is the challenge which Minnesotans have accepted.

All-out Effort Needed

To do the job—to acquaint and educate the public with sane and sound food and nutrition information—required the interest and co-operation of everyone. It requires the help of leaders and representatives of civic, business and industry, church, labor, educational and professional groups including the Parent-Teacher Associations, the Chamber of Commerce, the Better Business Bureau, the YWCA, Rotary, Kiwanis and other organizations in the community.

In the words of Philip L. White, M.D., Secretary of the Council on Foods and Nutrition, American Medical Association, "We consider this a vital education campaign, and we invite your support in exposing the food faddists and the promoters of eccentric diets whose fraudulent claims are luring a large segment of the American people away from sound nutritional habits and competent medical care."

Your Help Also Needed

Because the nutrition quack can endanger the entire community, undermine its confidence in common, everyday foods, and scoff at the necessity of competent medical care, various organizations and industries have a place in this program.

The medical profession of your community should be prepared to assist you in disseminating health education information to the general public through meetings, club programs, schools, fairs, church groups, unions, newspapers, magazines, television and radio.

Can We Help You?

The Minnesota State Medical Association is interested in the progress and success of this program, and we want to be of the greatest possible assistance to you. Please let us know when we can help, and we would appreciate hearing of your plans.

The following are available from the State Office.

** "The Merchants of Menace"—Eight-page two-color pamphlet, outlining the dangers of food faddism. Available in quantity without charge.

** "Let 'Em Eat Hay"—Reprint of an article in the September, 1958, issue of *Today's Health,* presenting a comprehensive review of food quackery and nutrition nonsense. Available in quantity without charge.

** "The Medicine Man"—Twenty-seven minute, black and white motion picture, produced in Hollywood especially for this campaign. Available for both television and community groups. No charge.

** "Nutrition Nonsense and False Claims"—A major, ten-foot exhibit for use at fairs and large meetings. No charge; pay only round-trip transportation costs. Please request well in advance of expected showing.

Mrs. Gaynold Jensen, *Chairman*
Community Nutrition Section
Minnesota Dietetic Association

PHYSICIANS URGED TO USE "MD"

Doctors of Medicine are urged to use "MD" after their names to distinguish them from all other kinds of doctors in the world today.

The American Medical Association will encourage such use of "MD", following the recommendation of the House of Delegates. "The term 'Dr.' is commonly used today to preface the names of doctors of chemistry, laws, divinity, and others, including those in the practice of cultism and quackery, as well as those in the practice of medicine," said a resolution adopted by the House.

The American Medical Association and your State Association will seek "to inform the public of the meaning of 'Doctor of Medicine' as contrasted with other 'doctor' designations."

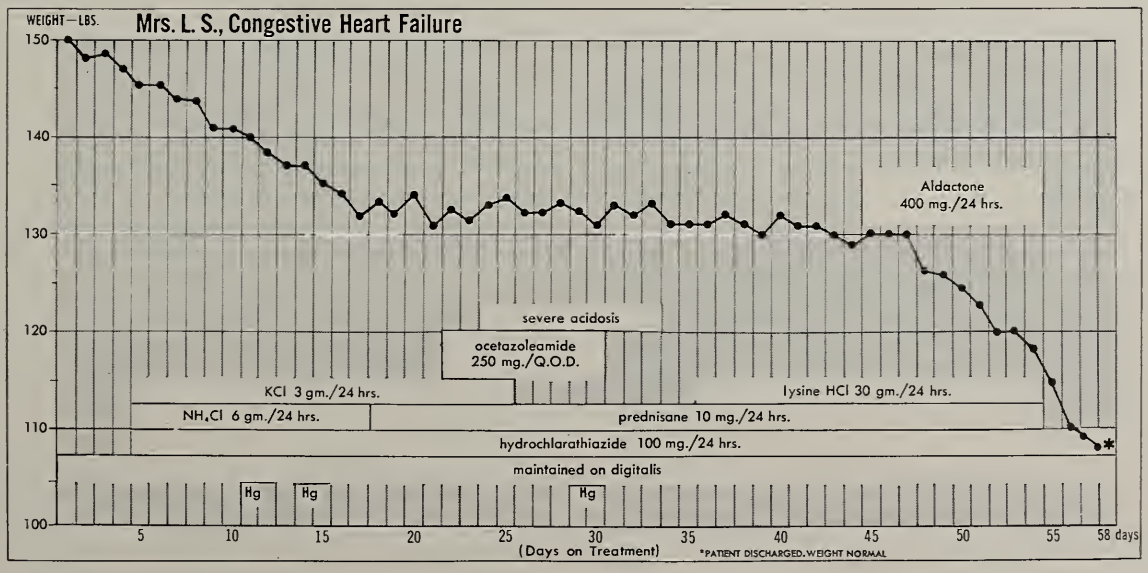
WHY *ALDACTONE*®

IN EDEMA

Because it acts by regulating a basic physiologic imbalance, Aldactone possesses multiple therapeutic advantages in treating edema.

Aldactone inactivates a crucial mechanism producing and maintaining edema — the effect of excessive activity of the potent salt-retaining hormone, aldosterone. This corrective action produces a satisfactory relief of edema even in conditions wholly or partially refractory to other drugs.

Also, Aldactone acts in a different manner and at a different site in the renal tubules than other drugs. This difference in action permits a true synergism with mercurial and thiazide diuretics, supplementing and potentiating their beneficial effects.



Further, Aldactone minimizes the electrolyte upheaval often caused by mercurial and thiazide compounds.

The accompanying graph shows a dramatic but by no means unusual instance of the effect of Aldactone in refractory edema.

The usual adult dosage of Aldactone, brand of spironolactone, is 400 mg. daily. Complete dosage information is contained in Searle New Product Brochure No. 52.

SUPPLIED: Aldactone is supplied as compression-coated yellow tablets of 100 mg.

G. D. SEARLE & CO., Chicago 80, Illinois.
Research in the Service of Medicine.

Minnesota Blue Shield

New Headquarters

Minnesota Blue Shield, on July 15, moved to its new headquarters at 2218 University Avenue, St. Paul, seven blocks from the Blue Cross building, where it had previously maintained offices.

The new location is a three-story building, with basement, totaling 24,000 square feet, which Blue Shield purchased earlier this year. Since then, extensive remodeling and alterations have been made in preparation for the move.

Administrative offices and the Division of Enrollment and Service occupy the first floor. The second floor houses IBM high-speed data-processing equipment for handling accounting and record-keeping functions. The IBM units had been in operation for some time at the new headquarters, in advance of the move. The claims department is located on the third floor. Also included in the new building is an employe's cafeteria.

The move, which began after business hours on Friday, was made without any interruption of service, with Blue Shield personnel resuming work in their new offices the following Monday morning.

Commenting on the move, Dr. Richard R. Cranmer, Executive Director of Minnesota Medical Service, Inc., said:

"Our new headquarters will give Blue Shield a more economical yet completely adequate home, with more than double the amount of square footage available than formerly. Our new home will also make possible the more efficient location of all our departments to provide prompt service for the more than 800,000 Minnesota Blue Shield subscribers."

Blue Shield subscribers, Doctor Cranmer added, represent about one-quarter of the total population of Minnesota.

Vice President Layton Urges Professional Cooperation

Dr. Ira C. Layton, Vice President of the Blue Shield Plan in Kansas City, in a recent address before the Kentucky State Medical Association's annual County Society Officers' Conference, analyzed the pressures being brought for government intervention in the medical care field and urged stronger co-operation of the medical profession with Blue Shield as the best answer to these pressures.

Doctor Layton said. "Certainly the requests of the public for increased scope of benefits, more adequate fee schedules whether on a service or indemnity basis, will be met and must be met by the doctor's plan if the practice of medicine is to survive in its present form."

He added that Blue Shield and the medical profession in this country are mutually dependent, for Blue Shield would not survive long in the area it serves without the medical profession's support, nor would the independent practice of medicine last long in the absence of Blue Shield.

New Challenges Lie Ahead

Also, while Blue Shield has thus far met the challenge and effectively answered critics of voluntary prepayment plans, new challenges continually lie ahead.

In our effort to save the free and voluntary system of health care, we must remind our critics—and ourselves—that Blue Shield has made a most significant contribution to the nation's public health. By pioneering in community-wide prepayment programs, it has assumed risks that commercial companies had previously declined to undertake. Yet, by setting the pace for health-care programs, Blue Shield eventually led these same commercial companies to devise health care programs of their own. As a result, more than 127 million Americans, or 72 per cent of the civilian population. were covered by some type of health insurance by the end of 1959.

Benefit payments by all forms of health care plans in 1959 totaled $4.3 billion.

Although these payments represent a tremendous impact on our economy, the real value of such widespread voluntary coverage—which Blue Shield pioneered—is beyond measuring, for the nation's public health is far sounder as a result. Prepayment coverage has encouraged our citizens to seek timely medical care and they and the nation have reaped immense benefits because of this.

Meanwhile, Minnesota Blue Shield has taken further pioneering steps, by adding such innovations as coverage for diagnostic, x-ray, and laboratory service benefits within standard contracts. This cannot but encourage still earlier diagnosis of what might have proven major disorders were not such diagnostic coverage available.

Blue Shield can, indeed, be proud of its past record and its promise for the future, and participating physicians can likewise be proud of their association with such an organization. When the public more fully understands these significant contributions by Blue Shield, pressures for governmental involuntary methods should abate, in favor of confidence in a program that has stood well the test of time and helped maintain the high standards of medical practice in this country.

6-10 HOURS
SUSTAINED THERAPY

ONE *and only* ONE
Timed AMO*dex* CAPSULE
PER DAY *will economically*

control appetite in weight reduction or relieve the nervous symptoms of anxiety and the underlying depression.

Timed AMO*dex CAPSULES* (Testagar) furnish a controlled uniform action. The medications provide prolonged, continuous therapeutic effect from active ingredients over a period of 6 to 10 hours.

Following ingestion of one *Timed* AMO*dex CAPSULE,* small amounts of the medication are released immediately.

Each *Timed* AMO*dex CAPSULE* contains a daily therapeutic dose of:

Dextro-amphetamine hydrochloride	15 mg.,
Amobarbital	60 mg.

PROTRACTED THERAPEUTIC EFFECT

Before the development of *Timed* AMO*dex* (Testagar) the usual dose of Dextro-amphetamine hydrochloride, for the control of appetite, was one 5 mg. tablet two or three times a day. The usual dose of Amobarbital ranged from 20 to 40 mg., two or three times a day. On such a dosage regimen the absorption of the drugs, after ingestion, takes place quite rapidly. The therapeutic activity occurs within one-half to one hour. When the therapeutic peak is reached, a gradual decline takes place. At this point, the patient should receive another dose of medication . . . the cycle is then repeated.

Patients frequently fail to follow the physician's instructions. They take medication at irregular intervals. When this occurs with drugs such as dextro-amphetamine sulfate, phosphate or hydrochloride, excitation may result. A balanced combination of Dextro-amphetamine hydrochloride, **the preferred salt,** plus a balanced daily dose of Amobarbital will give the expected therapeutic results *without* excitation.

Timed AMO*dex,* after ingestion, releases Dextro-amphetamine Hydrochloride and Amobarbital steadily and uniformly over a period of 6 to 10 hours. Therefore, the physician may dispense with the usual dosage schedule thereby *attaining better control of therapy.* The patient will receive the benefits of even and sustained therapeutic effects. Side reactions such as anxiety and excitation are greatly minimized.

AMO*dex* ADVANTAGES

- HIGH-LEVEL ANOREXIGENIC ACTIVITY WITHOUT NERVOUS EXCITATION
- SMOOTH, UNIFORM ACTION
- THERAPEUTIC EFFECT LASTING 6 TO 10 HOURS
- ONLY ONE DOSE DAILY
- CLINICALLY ECONOMICAL TO THE PATIENT

ACTION AND USES

Timed AMO*dex CAPSULES* (Testagar) supply the antidepressant and mood-elevating effects of Dextro-amphetamine hydrochloride and the calming action of Amobarbital. *Timed* AMO*dex* elevates the mood, relieves nervous tension, restores emotional stability and the capacity for mental and physical effort.

INDICATIONS

Timed AMO*dex* is the preferred treatment in anxiety states and in the management of obesity. *Timed* AMO*dex* may also be used in the treatment of Depressive states, Alcoholism, Nausea and Vomiting of Pregnancy.

DOSAGE The Daily Dose of *Timed* AMO*dex* (Testagar) IS ONE CAPSULE ON ARISING OR AT BREAKFAST.

SUPPLIED Bottles of 100 and 1000 capsules, available at all pharmacies. Also supplied in half strength as *Timed* AMO*dex,* Jr.

Timed AMO*dex CAPSULES* are manufactured under these patent numbers:
2,736,682 — 2,809,916
2,809,917 — 2,809,918
Which provide prolonged, continuous therapeutic effect over a period of 6-10 hours

DETECTION OF GASTRIC CANCER BY RADIOAUTOGRAPHY

My Dear Colleagues:

Radioactive phosphorus has been found to be extremely useful in the detection of gastric cancer in man. Greater experience is needed in the appraisal of the value of the method in difficult diagnostic gastric problems, in which roentgen or clinical techniques fail to clarify the exact nature of the lesion. Through the generosity of the American Cancer Society, monies have been obtained to support such a pilot study without cost to the patient.

Gastric cancer appears to be a diminishing disease. The free flow of patients with gastric cancer that came at an earlier date is not so much in evidence now. We would welcome the opportunity therefore of evaluating any available difficult diagnostic problems by this technique. If any cases are sent to the University Out-Patient Clinic, for the purpose, we would welcome receiving from the referring physician a brief statement together with recent, as well as earlier, x-ray films.

The patient under conventional circumstances would be managed as an out-patient with a half-a-day's hospitalization, following which he would be returned to his physician with a statement concerning our findings.

Our experience to date, though limited, would suggest that mucosal gastric cancer can be detected by this method. The patient ingests 500 microcuries of radioactive P32 twenty-four hours before the beginning of the test. A small deflated balloon coated with a photosensitized emulsion is swallowed, by the patient in a dark room, following which he returns to his bed for four hours. Extubation is performed in the darkroom and a cancer, if present, becomes apparent at once as a dark spot on the balloon, owing to the greater affinity of malignant tissue for P32, contrasted with the contiguous normal gastric mucosa.

It is the time factor of prolonged exposure which makes it possible to detect gastric cancer by this means. In all patients examined to date, when gastric cancer has been present, it has been correctly identified. The method also has important confirmatory value in the presence of positive x-rays. In mucosal gastric cancers in which all known available techniques of cancer detection are notably inefficient, it is believed that the technique described herein will prove useful, even in early gastric malignancies with poorly defined symptoms.

Any physician desiring to avail himself of this service for his patient, and without cost, may do so, by communicating with this Office. You may find we may be of some help to you and you can be of great help to us.

Owen H. Wangensteen, M.D.
Chairman, Department of Surgery
University Hospitals

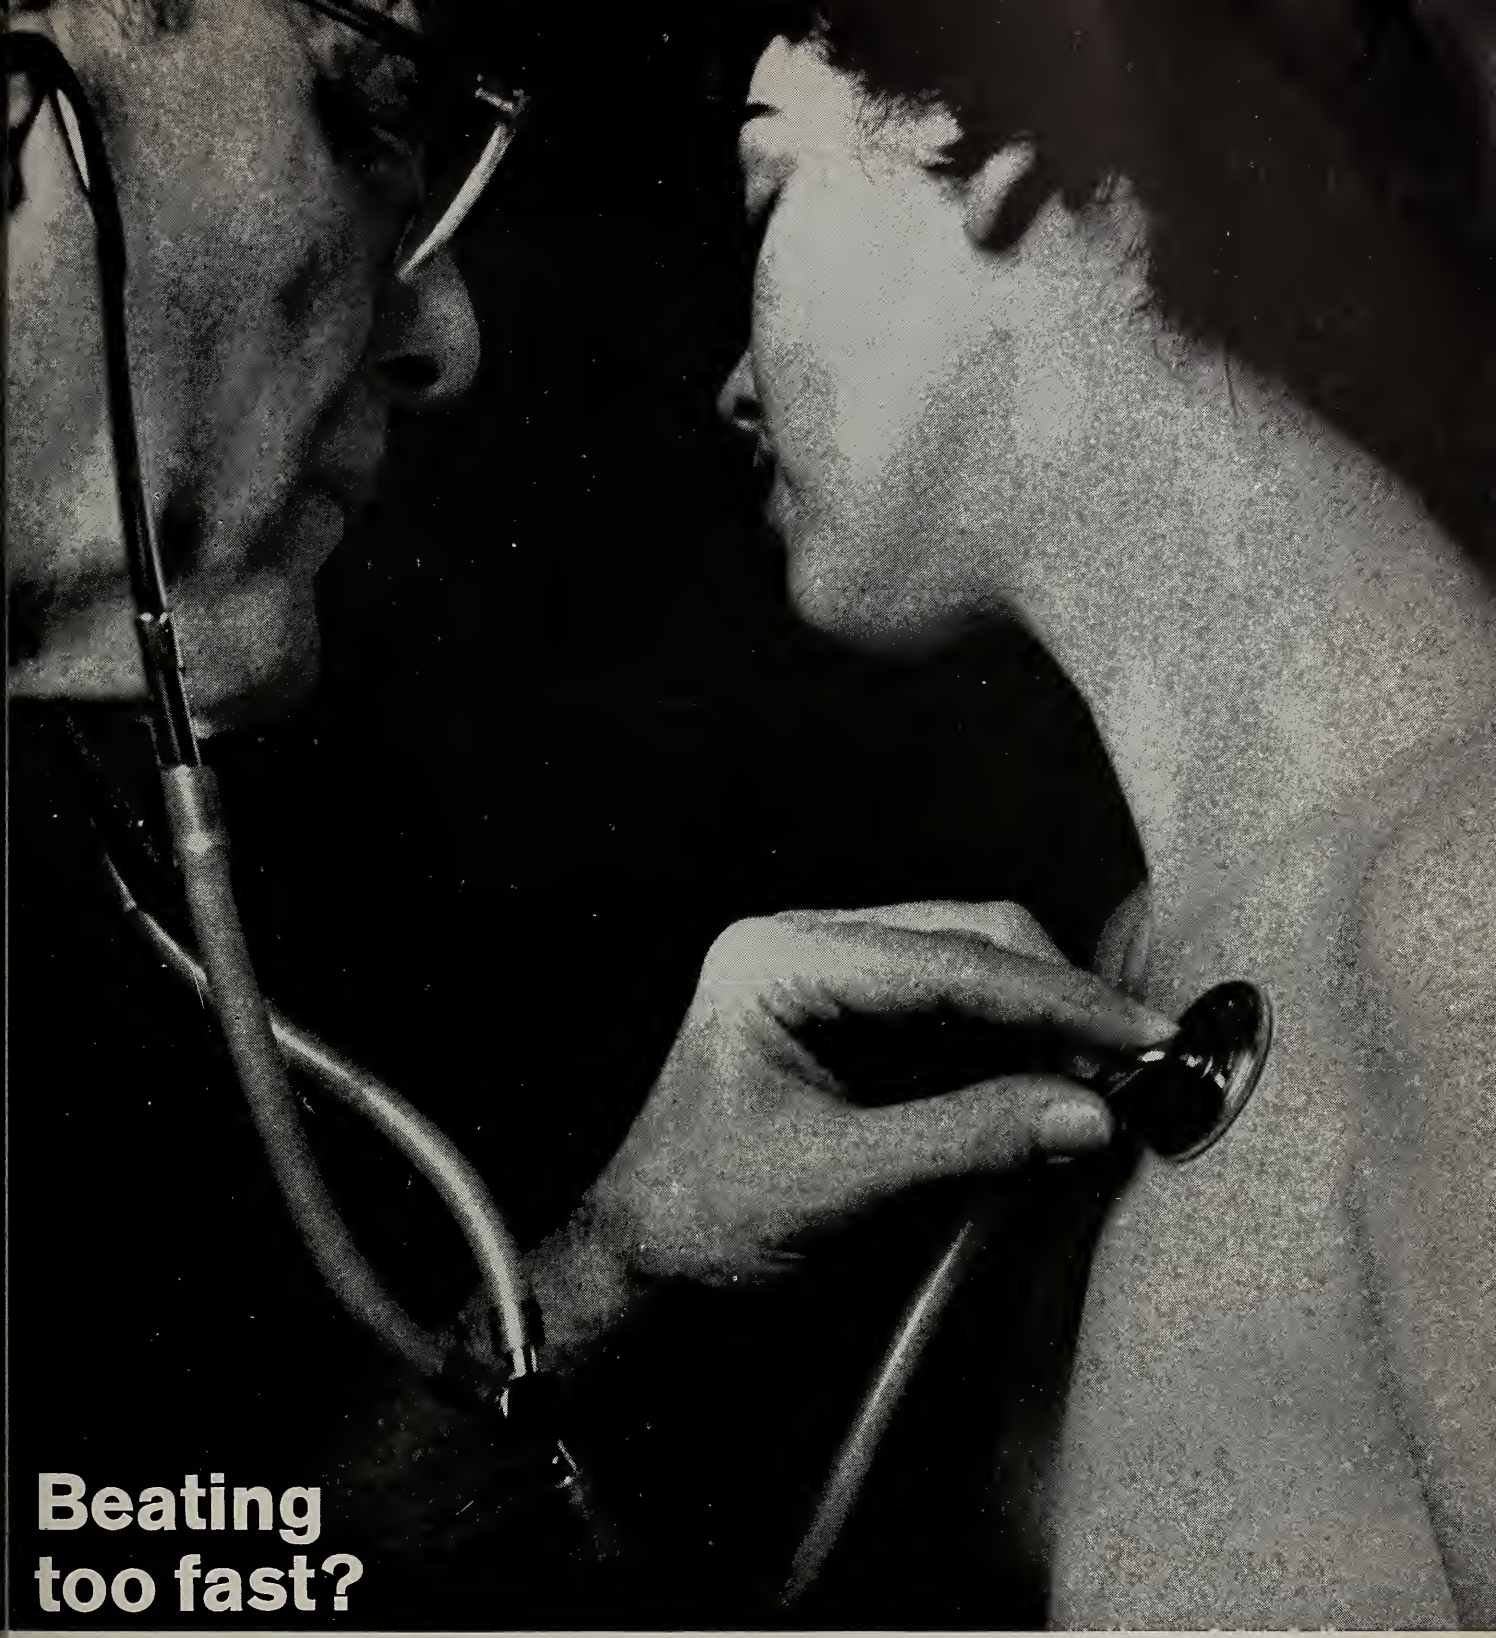
This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

FORMATION OF ADVISORY COUNCIL FOR NBC-RCA MEDICAL RADIO SYSTEM

The formation of an Advisory Council for the NBC-RCA Medical Radio System was announced May 18 at the fourth meeting of the System's Editorial Board in New York. The Council will be composed of fifty-five panels representing all leading specialties in the field of medicine. It was announced that ninety physicians had accepted positions on the Council. Additional panel members will be appointed with the Council roster expected to total 150.

Each of the fifty-five panels will be made up of from three to five or more outstanding doctors in each specialty. Physicians accepting the nominations will advise the Editorial Board on developments in their particular specialty. In addition to this, they will act as consultants, participate in programs of the Medical Radio System, and write papers on their specialty. The panel members, together with the Editorial Board, and the System's Medical Editor, Dr. Cornelius H. Traeger, represent an assemblage of outstanding leaders in the field of medicine.

Dr. Chester Scott Keefer, Editorial Board Chairman and President of the American College of Physicians, presided at the meeting.



Sale offices for doctors' subscriptions have been established in New York, Chicago, Los Angeles, San Francisco, Boston, Baltimore, Washington, Philadelphia, Pittsburgh, Atlanta, Minneapolis-St. Paul, and Dallas-Fort Worth.

Field testing of the especially designed FM Multiplex equipment has been completed and an announcement of the on-the-air date will be forthcoming shortly.

ULMER

LABORATORY REAGENTS and stains

New CATALOG

If you haven't already received your free copy of our new 64 page catalog of clinical Reagents and Stains, write for same today. It lists all of the more commonly used laboratory reagents and stains. You will find it very helpful.

ULMER REAGENTS AND STAINS HELP ACHIEVE ACCURACY

It is our objective to produce the finest reagents obtainable for clinical laboratory use. Their consistent accuracy saves hours of the technician's time.

Our scientific laboratory control is your assurance that Ulmer reagents are always fresh and meet the most exacting standards for each procedure. Every step of the manufacturing process is checked from the raw materials to the finished product. Moreover, our chemists are available to assist with any procedures with which you may be experiencing difficulties. Do not hesitate to call on them for assistance or advice.

For prompt and efficient service as well as guaranteed satisfaction, insist on Ulmer Reagents and order them direct from P & H.

In Memoriam

JACOB S. BLUMENTHAL

Dr. Jacob S. Blumenthal, Minneapolis physician, died July 3, 1960, at the age of sixty.

Doctor Blumenthal had been a member of the School of Medicine faculty at the University of Minnesota for thirty years. He was a staff member of Mt. Sinai, St. Andrews, St. Barnabas, Minneapolis General and the University Hospitals.

Doctor Blumenthal was born in Roumania and received his preliminary education from North High School and the University of Minnesota in Minneapolis. His medical education was obtained at the University of Minnesota Medical School from which he graduated in 1923.

Doctor Blumenthal was a member of the Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association. In addition, he belonged to the Minneapolis Pathology Society, the Minneapolis Society of Internal Medicine, the Minneapolis College of Chest Physicians, and other professional groups. He was a veteran of World War I and was a member of the American Legion.

Survivors include his wife, Hannah; one son, Dr. Malcolm N. Blumenthal, Minneapolis; a daughter, Mrs. Myra Lou Shapiro, Lansing, Michigan; a brother, Carl, Minneapolis, and three grandchildren.

CLAUDE L. HANEY

Dr. Claude L. Haney, one of Duluth's oldest practicing physicians, died June 15, 1960. He was eighty years of age at the time of his death.

He was born in 1880 in Austin, Minnesota, and received his preliminary education at Austin High School, and the University of Minnesota. His medical education was obtained at the University of Minnesota Medical School from which he graduated in 1906. His internship was served at St. Mary's Hospital in Duluth and he practiced medicine there since.

Doctor Haney was active in civic affairs, serving twelve years on the Board of Education and in Masonic circles. During World War I, Doctor Haney was a captain in the army medical corps. He was also a member of the Duluth Selective Service Board during World War I.

In 1937, Doctor Haney terminated his service on the School Board. He was treasurer in 1935-36.

Doctor Haney was a member of the West End American Legion Post, a life member of the St. Louis County Medical Society and the American Medical Association. He received his life membership in the Minnesota State Medical Association in 1950 and his fifty-year club membership in 1957.

He was a past potentate of Aad Temple, Shrine, member of Trinity Lodge, AF & AM, Duluth Scottish Rite bodies and Knights Templar.

Surviving are his wife, Elsie F.; a daughter, Mrs. Ancel Keys, St. Paul, and three grandchildren.

KANO IKEDA

Dr. Kano Ikeda, well-known pathologist at a number of hospitals in St. Paul for many years, died June 26, 1960. Doctor Ikeda was seventy-three years of age at the time of his death.

Doctor Ikeda was born in Tokyo, Japan, in 1886 and received his preliminary education at Tokyo, Japan, and Fusan, Chosen, Korea. He attended the Battle Creek College in Battle Creek, Michigan, after coming to the United States in 1904. He graduated from the College of Medicine, University of Illinois, in 1911, and served his internship at Asbury Hospital in Minneapolis. He was at the University of Minnesota on a teaching fellowship in bacteriology and pathology from 1916 to 1918.

Doctor Ikeda was Director of Laboratory and Pathology in Miller Hospital from 1929 until his retirement last December, 1959. During those years, he served in the same capacity at Children's Hospital, Gillette Hospital for Crippled Children and Riverview Memorial Hospital. He was also consulting pathologist in Midway and Mounds Hospitals and served as associate professor of pathology in the medical and graduate schools at the University of Minnesota and was professor of medical technology at Macalester College.

Doctor Ikeda was a member of the American Association for Cancer Research, the American Association of Pathologists and Bacteriologists and the Ramsey County Medical Society, the Minnesota State Medical Association and the American Medical Association. He belonged to the American Society of Clinical Pathologists, having served on the Executive Committee from 1934 to 1937 and as Secretary of the Board of Registry from 1929 to 1942.

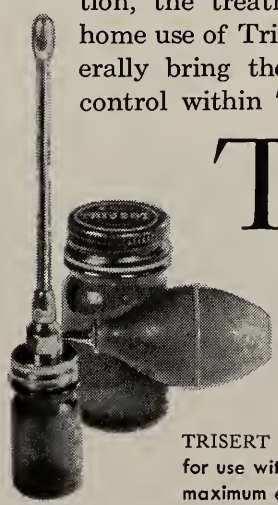
He was associated with the International Association of Medical Museums, Radiological Society of North America, a fellow in the College of American Pathologists, a fellow in the American College of Physicians and the Minnesota Pathological Society, in which he had been president. He was also a member of the Minnesota Society of Clinical Pathologists, in which he served twice as president and several terms as secretary.

Survivors are his wife, Mae; a daughter, Ethel M. of West St. Paul; a son, Alden T. Ikeda, St. Paul; three grandchildren, and a brother in Japan.

HENRY P. LINNER

Dr. Henry P. Linner, Minneapolis, died June 25, 1960, at his summer home at Lake Minnewashta. Doctor Linner was eighty-one years old.

Born at Chisago City, Minnesota, in 1879, he received his preliminary education at Gustavus Adolphus College, in St. Peter, Minnesota. He attended the University of Minnesota Medical School and graduated from there in 1909. He served his internship at Swedish Hospital in Minneapolis.



King Gustav of Sweden made him a Knight in the Order of North Star in recognition of his contributions to Swedish-American relations. He also received the royal order of Vasa award.

Doctor Linner was a member of the Board of Gustavus

For fast, complete treatment of vaginal infections

Problem is: she'll wait until discomfort is acute and then expect immediate relief. The answer is Trisert. Trisert preparations contain ALLANTOIN, an effective debriding agent which quickly dissolves heavy mucus often accompanying vaginal infections . . . METHYLBENZETHONIUM CHLORIDE, a quaternary germicide which removes unpleasant odors . . . SUCCINIC ACID, an aid in maintaining optimal vaginal pH . . . 9-AMINOACRIDINE HYDROCHLORIDE which has been included to supplement the bactericidal and trichomonacidal activity of other constituents. Treatment with Trisert Powder will control symptoms fast . . . usually within an hour . . . and provide effective initial treatment for 48 hours. After a second insufflation, the treatment is completed with at home use of Trisert Tablets which will generally bring the infection under complete control within 7 days.

Trisert

TRISERT TABLETS—Patient set, contains bottle of 30 tablets and special inserter. Bulk bottle of 100 tablets.

TRISERT POWDER—Available in 4 gr. individual treatment bottles. 12 to carton.

TRISERT POWDER INSUFFLATOR—Designed for use with Trisert Powder. Its use is urged for maximum efficiency.

THE ULMER PHARMACAL COMPANY

1400 Harmon Place • Minneapolis 3, Minn.

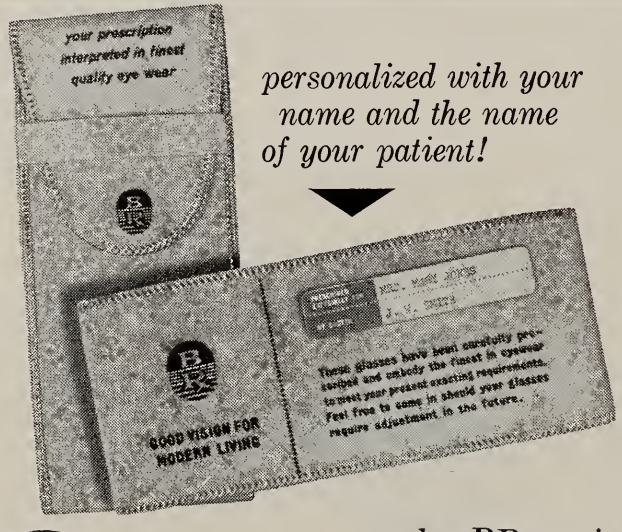
Adolphus College in St. Peter and the First Federal Savings and Loan Association in Minneapolis. He was a member of the Hennepin County Medical Society, a life member in the Minnesota State Medical Association and a member of the American Medical Association. In 1959, Doctor Linner was granted membership in the Fifty Club of the Minnesota State Medical Association. He was a former Chief of Staff at Swedish Hospital and a member of the Hospital's Board for twenty-nine years.

Surviving are his wife, Amanda; two sons, Dr. John H., Edina, and Dr. Paul W. Linner, Minneapolis; two daughters, Mrs. Morley (Carol) Seagren, St. Louis Park, and Mrs. Lewellyn (Melba) Kolstad, Hopkins; and two brothers, Edward Peterson, Chisago City, and Carl Peterson, Minneapolis.

FRANK M. MANSON

Dr. Frank M. Manson, last of Worthington's early-day physicians, died June 10, 1960, at the age of eighty-nine years.

Doctor Manson was born in 1871 at Pine Bend, Minnesota. He grew up at Shakopee where he received his preliminary education. He attended the University of Minnesota Medical School, receiving his Doctor of Medicine degree in 1899. He set up a permanent practice in Worthington, establishing the Worthington Hospital in 1906.



During World War I, he served as Chief of the Surgical Service at Camp Dodge, Iowa, and received special recognition for his work during the influenza epidemic.

Doctor Manson was a fellow of the American College of Surgeons, a member and President of the Kiwanis Club and of the Civic and Commerce Association. He was an associate member of the Minnesota State Medical Association, the Southwestern Minnesota County Medical Society and the American Medical Association.

Doctor Manson is survived by two sons, Dr. Melville Manson, Isles of Pines, Cuba, and Dr. Emmett Manson in Rhode Island, also two grandsons.

The Physician's Diary

University of Minnesota Professor of Medicine, **Dr. Wesley Spink,** has been appointed to a Board of Physicians to review decisions of Doctor Henry Welch, ousted head of the Food and Drug Administration's Antibiotics Division. Arthur S. Flemming, Secretary of Health, Education and Welfare, named eight physicians to the Board.

* * *

A St. Paul woman physician, **Dr. Marguerite Schwyzer,** one of the newest to join Dr. Tom Dooley's MEDICO task force, reported for work recently in Haiti. Doctor Schwyzer is the sister of **Dr. Hanns Schwyzer,** St. Paul. She will be part of a team of six specialists fighting special disease problems in Haiti. After graduating from Yale University Medical School, she practiced in Massachusetts, Illinois, New York and California. The last six years she has worked with Wilder Dispensary and the University of Minnesota Student Health Service. Doctor Schwyzer, a specialist in internal medicine, became interested in MEDICO after meeting Doctor Dooley, one of the men who set up the organization, when he lectured in St. Paul. She expects to stay with MEDICO for one year.

* * *

The Upper Mississippi Mental Health Center announces the appointment of **Dr. Howard C. Reid,** Amarillo, Texas, as psychiatrist and administrator. Doctor Reid assumed his duties about May 1. **Dr. D. E. Hoganson,** Bemidji, is a member of the Upper Mississippi Mental Health Board.

* * *

Dr. John Hendrickson is now associated in the practice of medicine with **Dr. Les N. Dale** at the Red Lake Falls Clinic. His association became effective July 1.

* * *

Dr. Edmund B. Flink, Chief of Medical Services at the Minneapolis Veterans Hospital, has been appointed Professor and Chairman of the Department of Medicine at West Virginia University in Morgantown, West Virginia.

* * *

New officers of the Minnesota Academy of Ophthalmology and Otolaryngology for the 1960-1961 term of office are as follows: President, **Paul G. Bunder, M.D.,** Aberdeen, South Dakota; First Vice President, **John A. McNeill, M.D.,** St. Paul; Second Vice President, **Benjamin Bofenkamp, M.D.,** Minneapolis; Secretary-Treasurer, **Richard O. Leavenworth, Jr., M.D.,** St. Louis Park. Council members are: **W. T. Wenner, M.D.,** Chairman, St. Cloud; **Thomas Kirby, M.D.,** Rochester; **Douglas R. Kusske, M.D.,** St. Paul; **Walter Lees Hoffman, M.D.,** Minneapolis; and **W. J. Bushard, M.D.,** Minneapolis.

Dr. Herbert E. Warden, one of the team of four University of Minnesota heart surgeons which pioneered open heart surgery in 1954 is leaving the school. He has been appointed to the surgery staff of the new West Virginia Medical School in Morgantown. Doctor Warden was associated with Drs. **C. Walton Lillehei, Richard L. Varco, Morley Cohen** in the surgery. Doctor Warden is the second of the team to leave the University. Doctor Cohen left to return to his surgery practice in Winnipeg.

* * *

A former fellow at the Mayo Clinic, **Dr. Ralph Bowen, Jr.,** has left for Nairobi, Kenya, Africa, where he will be the second plastic surgeon in an area of six million people. Doctor Bowen is going to Africa for one year's study under a travel research grant sponsored jointly by the African Research Foundation and the Medical International Cooperation Organization. He is the only physician working with a newly created mobile unit that seeks out patients, especially those with skin cancer, which is especially prevalent in the area. After a year's study in Africa, Doctor Bowen plans to return to the United States and begin private practice.

* * *

Babbitt, Minnesota, has a new physician. He is **Dr. G. T. Stewart,** formerly of Mt. Ida, Arkansas. Doctor Stewart owned and operated a clinic in Mt. Ida for thirteen years before coming to Babbitt. He specializes in Obstetrics.

* * *

Newly elected officers of the Minnesota Chapter of the Flying Physicians Association for the 1960-1961 term of office are **Dr. O. M. Wilbur,** Hibbing, Minnesota, State Chairman: **Dr. C. H. Scheifley,** Rochester, state co-chairman, and **Dr. Roger S. Johnson,** Excelsior, safety and research state chairman. The Flying Physicians Association is a national organization with some 2000 member flying doctors whose aim is to promote flying safety, aviation health standards for crew members and passengers, and research into the complex problems of space medicine and aging processes of crew members.

* * *

Dr. Donald J. Erickson, Mayo Clinic, spoke at the meeting of the Downtown Kiwanis Club in Rochester. He also showed a film on paraplegia.

* * *

Six St. Paul physicians, all members of St. Joseph's Hospital staff, participated in ceremonies when the hospital's new operating suite was dedicated to the memory of their fathers. The plaque on the first floor of the new John Gregory Murray unit commemorates six surgeons who earned prominence while associated with the hospital. They are **Drs. William Carroll, John Culligan, David Hilger, Justus Ohage, Harry Ritchie** and **Arnold**

Schwyzer. All but Doctor Carroll were represented by sons who are on the staff. Two of Doctor Hilger's sons, both physicians, were among those attending. The sons are Dr. **John A. Culligan, Jerome** and **Laurence Hilger, Justus Ohage, Wallace Ritchie** and **Hanns Schwyzer.**

* * *

Professor of Anatomy at the University of Minnesota Medical School, **Dr. Arnold Lazarow,** has been honored by the University of Chicago Medical Alumni Association. He received the Association's Distinguished Service Award at the annual reunion banquet of the Association.

* * *

Dr. Roland G. Anderson, formerly of the Falls Clinic in Thief River Falls, has opened a private practice of general surgery. His office is located at 214½ LaBree Avenue North, Thief River Falls.

* * *

Members attending the recent dinner meeting of the Southwestern Minnesota Medical Society heard **Dr. William C. Bernstein,** St. Paul proctologist, speak on "Common Ano-Rectal Disorders." Also on the agenda was a discussion of subjects presented by **Dr. John Lohmann** and **Dr. Vernon Vix.**

* * *

Dr. John A. Sturgis, who practiced medicine in Lamberton for two and one-half years, has left to resume an orthopedic surgical residency at Hamot Hospital in Erie, Pennsylvania. Following the residency, Doctor Sturgis plans to remain in the middle eastern states where he will specialize in orthopedic surgery.

Dr. Donald Holm, formerly of Benson, began his residency for advanced study in radiology July 1. Doctor Holm was in practice with **Dr. Robert Nelson** in the Holm-Nelson Clinic in Benson for approximately seven years. Doctor Nelson is continuing his practice in Benson.

* * *

The physician who founded the St. Paul Children's Hospital was honored at an achievement dinner in the Women's City Club in St. Paul. **Dr. Walter R. Ramsey,** started the hospital in 1924. A wing of the new two-million dollar addition has been named the Ramsey Wing in honor of the doctor. Doctor Ramsey received a citation of achievement and gold disk bearing the hospital insignia. Members of the Board of Trustees, the active medical staff of the hospital, heads of departments of the hospital and others associated with the hospital attended the dinner.

* * *

Dr. Arthur C. Kerkhof, president of the Minnesota Heart Association, has announced that Grants-in-aid totaling $97,165 have been awarded to eleven Minnesota scientists for research on diseases of the heart and blood vessels. Minnesotans receiving the awards are: **Dr. Walter O. Lundberg, Richard A. DeWall, Robert A. Good, Ancel Keys, Victor Lober, Edward Ronwin, Henry L. Taylor, Louis Tobian** and **Cecil J. Watson,** all of the University of Minnesota; **Dr. Richard W. Von Korff,** Variety Club Hospital and **Dr. E. H. Wood,** Rochester.

MINNESOTA BLUE SHIELD

A Community Service

Blue Shield is a community service... offering pre-payment medical care protection to the citizens of Minnesota. Blue Shield has never cancelled a contract because of age, condition of health, or amount of benefits furnished. Today, Minnesota Blue Shield, with more than 800,000 subscribers, covers one-fourth of the State's population.

Minnesota Medical Service, Inc.
St. Paul 14, Minnesota

Dr. John S. Pearson, Mayo Clinic, will conduct Dr. Zenya Pluzek, a clinical psychologist in practice in Poland, through the facilities of the Mayo Clinic. Doctor Pluzek is in Rochester observing techniques in clinical psychology as applied at the University of Minnesota. She has translated a number of works on the subject from English into Polish.

* * *

Cloquet physician, **Dr. Marie K. Bepko,** recently attended the Seventh Congress of the Pan-American Medical Women's Alliance, which meets every two years, this year in Central America. En route home, she stopped in Miami to attend the American Medical Women's Association and the World Medical Association United States Committee meeting.

* * *

The newly formed Minnesota-Wisconsin-Iowa Societies of Oral Surgeons recently held a two-day session in Rochester. **Dr. S. A. Lovestedt** of the Mayo Clinic was General Chairman. **Dr. O. K. McKay,** Duluth, is president-elect of the organization.

* * *

Two University of Minnesota medical leaders participated in the dedication of the new addition to the Jay Phillips Research Laboratory at Mt. Sinai Hospital in Minneapolis. They were **Dr. Owen H. Wangensteen,** Chairman of the University Surgery Department, main speaker at the public ceremonies, and **Dr. C. Walton Lillehei,** Professor of Heart Surgery, addressed a dinner gathering.

* * *

Dr. James Oliver, formerly of Moorhead, recently joined the staff of the Veterans Hospital in Minneapolis for a three-year residency. Doctor Oliver will further his study in medicine, specializing in urology at the Minneapolis Veterans Hospital under the graduate program offered by the University of Minnesota.

* * *

Dr. B. J. Cronwell, Austin, was among 130 doctors from twenty states and three foreign countries attending a one-week postgraduate course in "Recent Advances in Internal Medicine" at Peter Bent Brigham Hospital.

* * *

Dr. J. C. Cain and Mrs. Cain, Rochester, have returned from a two and one-half month trip through England, Holland, Germany, Spain, Switzerland, France, Belgium and Italy. Doctor Cain attended a medical meeting in Holland at the beginning of the trip.

* * *

Dr. Andrew G. Sathe, a former resident of Moorhead, has opened medical practice in that city. Doctor Sathe was previously employed at the Harmon Clinic in Williston, North Dakota.

* * *

Mayo Clinic staff member, **Dr. Edward M. Litin,** gave the Higgins-O'Donnell Lecture at West Point, New York.

The lecture was established four years ago as a memorial to Doctor John Higgins, of Sayre, Pennsylvania, and Doctor Francis O'Donnell, Wilkes-Barre, Pennsylvania, who were prominent in the practice of pediatrics in northeastern Pennsylvania and whose lifetime work in that field provided an impetus to the founding of the Pediatric Society of Northeastern Pennsylvania. "Psychiatry and the Family Doctor" was the title of Doctor Litin's address.

* * *

St. Olaf College in Northfield, Minnesota, recently presented **Dr. Herbert W. Schmidt**, Mayo Clinic, with an award for outstanding achievement as an alumnus of St. Olaf College. Previously Doctor Schmidt had been elected a trustee of the college.

* * *

"The Rheumatic Fever Prophylaxis Program in Minnesota" was the title of a talk given by **Dr. John O'Leary** of Brainerd at the Conference on Physicians and Schools held at Cragun's Resort on Gull Lake. The Conference was sponsored by the Minnesota Heart Association, the Minnesota Department of Health, the Minnesota Department of Education and the Minnesota Association for Mental Health. Reason for the conference was to develop health environmental standards among children of school age through discussion of specific health problems. Nutrition and diet, accident prevention, emotional and physical environment and health instruction were some of the topics of the Conference.

anorectic-ataractic ®
BAMADEX
meprobamate 400 mg., with d-amphetamine sulfate 5 mg., Tablets

FOR THERAPY
OF OVERWEIGHT PATIENTS

- d-amphetamine depresses appetite and elevates mood
- meprobamate eases tensions of dieting (yet without overstimulation, insomnia or barbiturate hangover).

Dosage: One tablet one-half to one hour before each meal.

A LOGICAL COMBINATION
IN
APPETITE CONTROL

Lederle

MAIN BUILDING—One of 8 Units in "Cottage Plan"

A MODERN PRIVATE SANITARIUM
for the Diagnosis, Care and Treatment of Nervous and Mental Disorders

ST. CROIXDALE ON LAKE ST. CROIX
PRESCOTT, WISCONSIN

Located on beautiful Lake St. Croix, 18 miles from the Twin Cities, it has the advantages of both City and Country. Every facility for treatment provided, including recreational activities and occupational-therapy under trained personnel. Close personal supervision given patients, and modern methods of therapy employed. Inspection and cooperation by reputable physicians invited. Rates very reasonable. Special rates given to custodial patients.

Minneapolis, Minnesota

Presented at Minneapolis Academy of Medicine, Minneapolis, Minnesota, February 15, 1960.

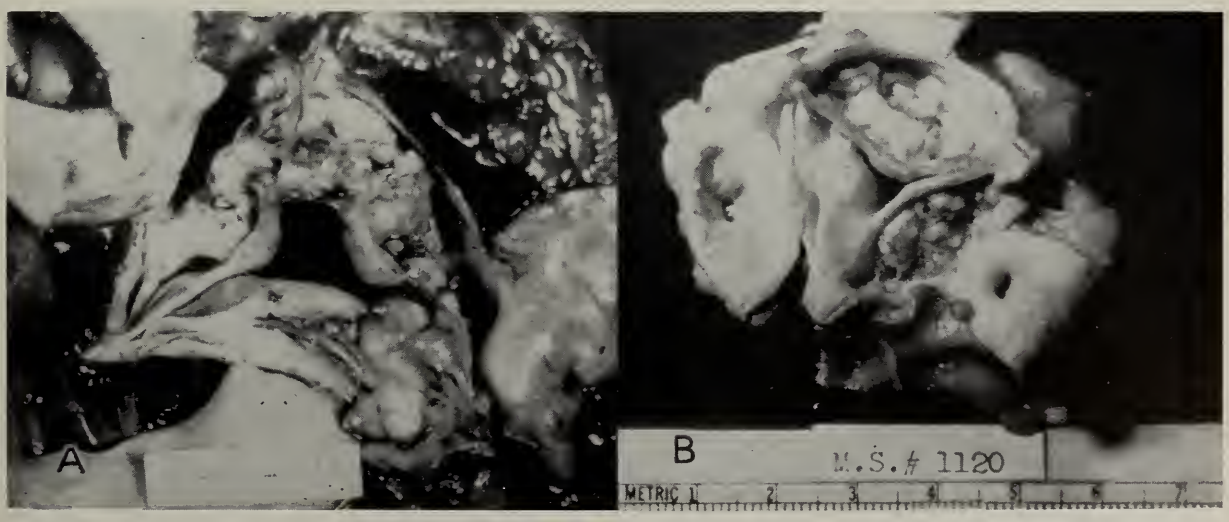

Fig. 3 a and b. Advanced disease of aortic valve with calcification and combined aortic stenosis and regurgitation.

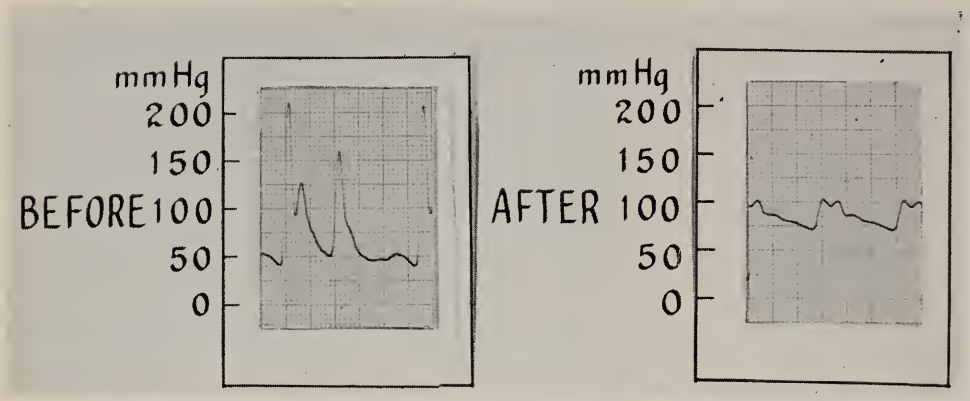

Fig. 2. Pulse curves before and after conversion of tricuspid aortic valve to bicuspid valve. Following formation of bicuspid aortic valve, the diastolic pressure rose from 35 to 75 mm. Hg.

ALTHOUGH initially open heart surgery was confined to only a few centers in this country, it was inevitable that with time and added experience these newer techniques would be practiced in many hospitals at home and abroad. Our clinical experience with the use of an extracorporeal pump oxygenator in Minneapolis private hospitals includes a variety of surgically remediable congenital and acquired forms of heart disease.

Among the most difficult of these are the stenotic and regurgitant lesions of the aortic valve. Reasons for this are immediately apparent, namely, (1) variations in pathologic anatomy, (2) limitations to correction due to pathologic anatomy, (3) the advanced stage of the disease associated with deterioration of the left ventricle when surgical intervention is considered, (4) special technical problems of cardiopulmonary bypass as air emboli follow aortotomy, the need for prolonged total body perfusion, the need for providing nourishment to the myocardium during surgical correction as by direct antegrade coronary perfusion.

Historical Background

In 1913, Tuffier[1] attempted surgical dilatation of aortic stenosis by invaginating the wall of the aorta, but surgery for aortic insufficiency remained

Supported by USPH Grant No. H-2610, John A. Hartford Foundation, Inc., and the Cardiac Research Committee, Minneapolis, Minnesota.

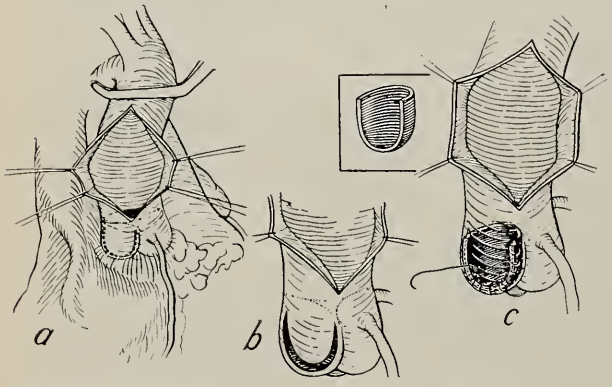

Fig. 4. Technique of aortic cusp substitution. (a) Broken line is the proposed line of incision opposite the noncoronary cusp. (b) Curvilinear incision is made through the aortic wall opposite the noncoronary cusp. (c) Cusp substitute is fitted into the curved aortic incision at the cusp level and sutured in place.

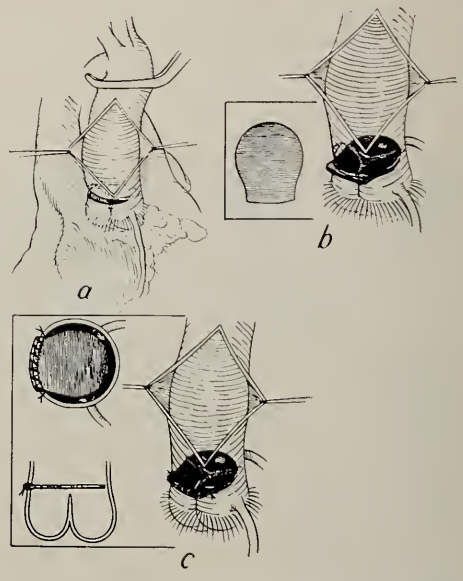

Fig. 5. Technique of supracoronary flap valve substitution. (a) Vertical aortotomy and transverse semilunar aortotomy distal to valve level. (b) A plastic flap valve is placed above aortic valve. (c) Flap sutured into position through full thickness of aortic wall.

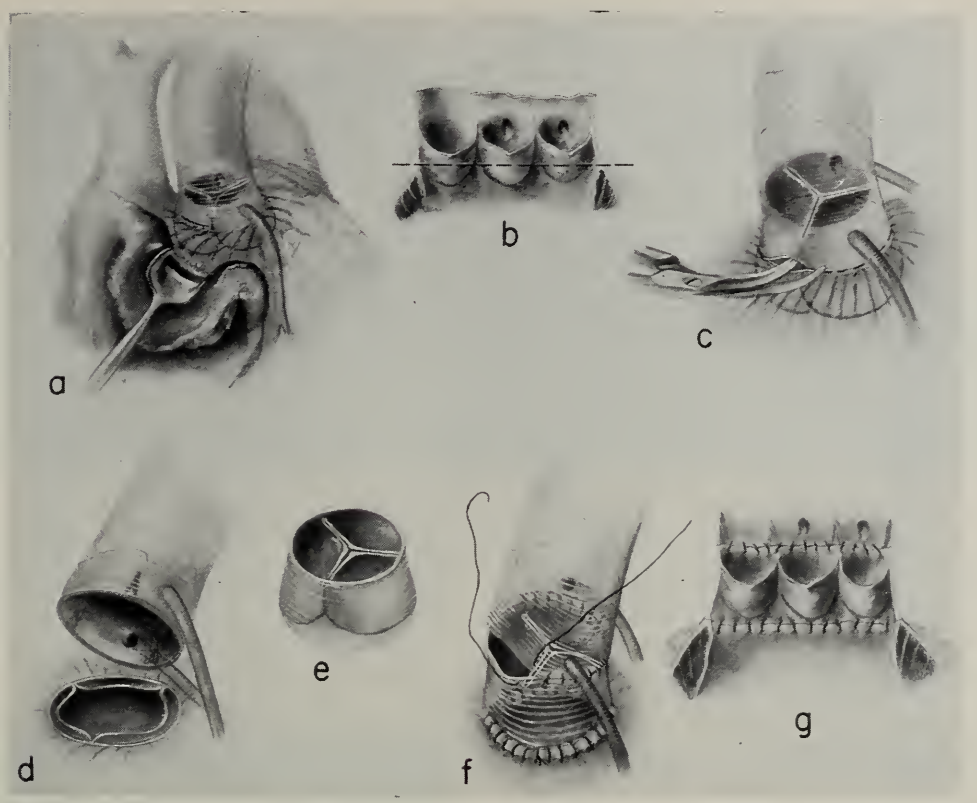

Fig. 6. Technique of subcoronary valve substitution. (a) Beginning of transection of aorta opposite the noncoronary cusp. (b and c) Level of complete subcoronary transection of aorta. (d) Aortic transection below coronary arteries completed. (e) Aortic valve substitute. (f and g) Aortic valve substitute fixed in position by direct suture anastomosis.

dormant until Campbell[2] in 1950 and Hufnagel[3] in 1951 introduced prosthetic valves in the descending part of the thoracic aorta. Other methods tried experimentally and clinically for the control of aortic regurgitation include:

(1) transplantation of homologous aortic valves in the thoracic aorta,[4,5,6] (2) fashioning of valve from intima of aorta,[7] (3) injection of sclerosing solutions at base of aorta,[8] (4) pericardial pedicles[9] and vein grafts[4] suspended above the aortic valve, (5) organic prosthesis substitutes,[10] (6) circumferential purse-string sutures of aortic annulus,[8,11] (7) supra- and subcoronary prosthetic valves.[8,12,13,14]

The ball-valve prosthesis of Hufnagel placed in the descending thoracic aorta received extensive clinical trial by him and although providing worthy palliation in a number of cases the limitations of the method are evident, such as, (1) partial control of the regurgitation because of the distal location of the artificial valve, (2) reversal of the relationships between the coronary arteries and the distally placed valve, (3) a permanent foreign body is introduced into the blood stream with possible sequelae of trauma to blood cellular elements and thrombus formation, (4) hazards of infection, aneurysm formation and rupture. Following clinical application in more than 400 patients, Hufnagel abandoned this method in favor of direct operative procedures.

The development of open heart techniques led to the direct vision attack on congenital and acquired aortic stenosis with hypothermia,[15,16] and total body perfusion,[17] and it is logical that the same approach should be applied to aortic insufficiency. Retrograde coronary perfusion[17,18] extended the operative time. Antegrade coronary perfusion[19-22] provided a method of nourishing the myocardium during exposure of the aortic valve. Hypothermia combined with perfusion[23] permits further extension of operative time. Although chemical cardioplegics as potassium citrate and acetylcholine are losing popularity, hypothermic cardiac arrest[24,25] has proved to be a satisfactory method.

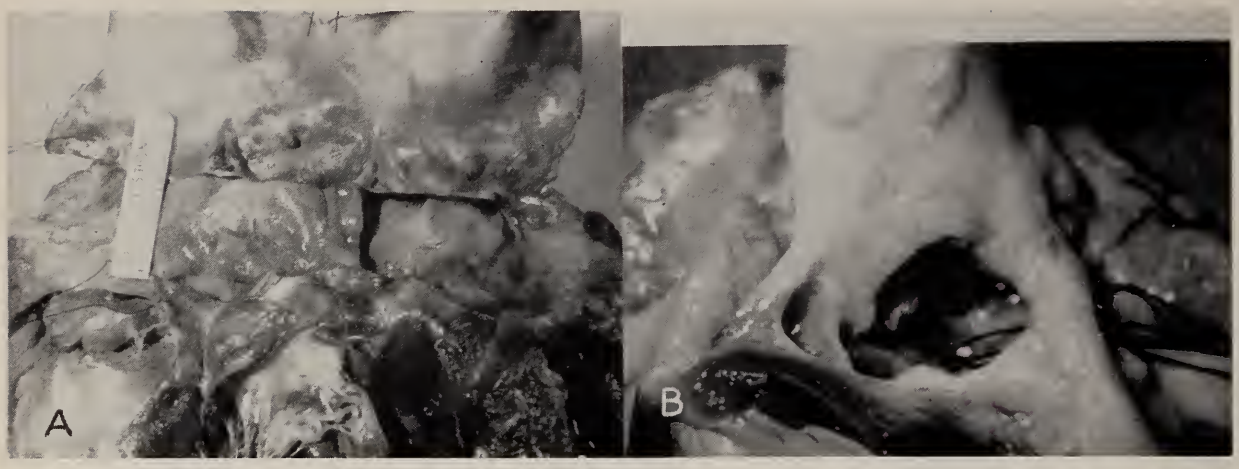

Fig. 7. *(above)* (a) In human autopsy specimen, the aorta is transected below the coronary arteries. (b) View showing a surprising stretch of the coronary arteries after the transection permitting a liberal separation of the margins of the divided aorta.

Presently, the following direct methods are being explored experimentally and clinically in the treatment of aortic insufficiency.

Direct methods of surgical correction are:

(1) conversion of tricuspid aortic valve to bicuspid valve,[26-32] (2) commisural suture to form a conjoint cusp,[17] (3) cusp restoration by suture,[17,30] (4) cusp restoration by prosthesis,[17,33] (5) cusp restoration by autogenous aortic wall,[30] (6) valve replacement, total.[8,12-14,34-36]

In previous communications, Garamella[26] and associates described a method of converting the triscuspid aortic valve to a bicuspid valve. Acute and chronic experimental studies and human post mortem anatomical studies[27-29] supported the clinical application of the method. Others (Bailey,[20,30] Lillehei,[37] Varco,[38] Hufnagel,[34] Creech,[31] Cooley,[32] and Kelly[39]) have clinically applied this method, or a modification.

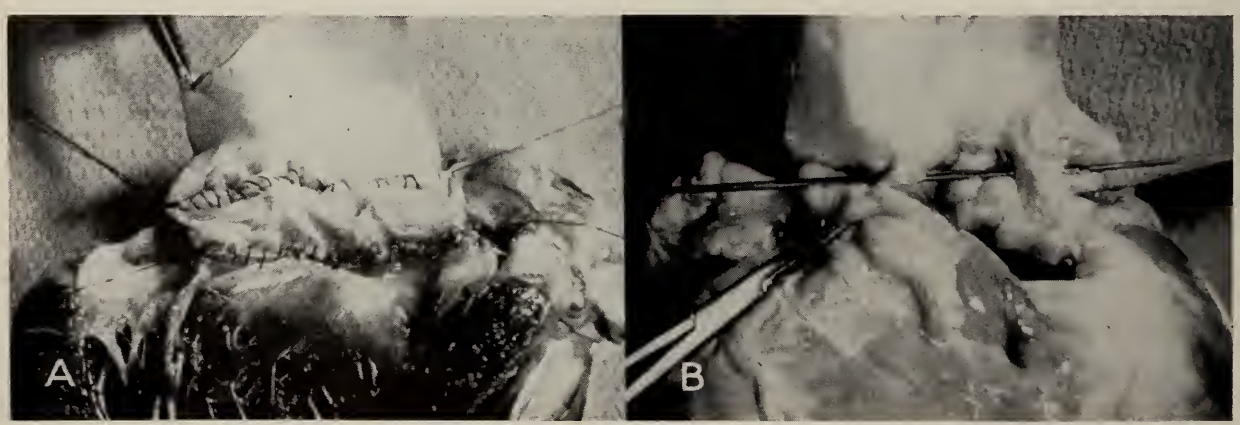

Fig. 8. Homologous aortic or pulmonic valve substitute.

Report of Cases

Our experience with this method has been limited to three cases, as follows:

Fig. 9. *(below)* (a) Substitute valve sutured in place below the coronary arteries. (b) View showing coronary arteries separated from substitute valve.

Case 1.—A forty-nine-year-old man had aortic insufficiency for many years. Two months before surgery he suffered his second bout of congestive failure. Combined right and left heart catheterization were done. Surgery was elected. At the time of pericardiotomy, a quantity of old, bloody fluid (900 cc) was present in the pericardial sac. Ventricular fibrillation occurred. Defibrillation was rapidly accomplished and the procedure was continued. A bicuspid aortic valve was formed, but sustained ventricular contractions could not be obtained after closure of the aortotomy. At autopsy, the heart weighed 750 grams. The reconstructed bicuspid valve appeared competent. Severe coronary disease and multiple, old infarcts were present.

Case 2.—A thirty-seven-year-old woman had known aortic insufficiency for several years. She developed sudden congestive failure and after rigid medical management was sent home for an additional six week period prior to surgery. During this period she again developed congestive failure. Following a suitable period of preparation surgery was undertaken. A bicuspid aortic valve was formed without difficulty. Failure followed, however, due to unequal sizes of the remaining aortic cusps and imperfect coaptation resulting in residual aortic incompetence (Fig. 1).

Case 3.—The patient was a thirty-three-year-old man who was found to have a heart murmer at age 16 when entering the Armed Forces. He was rejected for duty.

In May, 1959, he developed a febrile illness and subsequently subacute bacterial endocarditis with clinical aortic insufficiency. His clinical course was progressively downhill in spite of rigid medical management. He continued to have nocturnal dyspnea. Cardiac catheterization showed elevated wedge and pulmonary artery pressures. Surgery was elected.

A fenestrated non-coronary cusp was found and excised. A bicuspid valve was nicely fashioned. The postoperative blood pressure was 105/75, preoperative 175/35 (Fig. 2). Unfortunately, this patient died on the first postoperative day from air emboli.

In some instances, as in the second case described, and as shown in Figure 3a and b, the nature of the pathology causing aortic incompetence ideally demands partial or total valve substitution. A number of investigators have reported experimental methods of total valve substitution and indeed there are isolated reports of clinical use.[35,36] However, due to unresolved physiologic and technical problems, this procedure is not ready for broad clinical application.

One of the chief obstacles to success has been loss of valve function due to thrombosis following insertion. In addition, a method of fixation of the valve below the coronary arteries has proved difficult. To minimize these problems, several alternate methods of partial and total aortic valve substitution are under investigation and are schematically shown in Figures 4, 5, and 6. Anatomic studies are shown in Figures 7a and b, 8, 9a and b, and 10.

Fig. 10. Plastic valve substitute sutured in subcoronary position.

Operations were performed with cardiopulmonary bypass and total body perfusion supplemented with antegrade coronary artery perfusion or hypothermic cardiac arrest. Preliminary experiments indicate that this method of total aortic valve substitution is feasible. Animal hearts have resumed function following total valve substitution, the longest for fifty-two minutes. The principal cause of failure has been bleeding at the line of anastomosis. The anatomy is such as to make the anastomosis technically difficult. Continued experience with the method may eliminate this shortcoming.

Summary and Conclusion

1. In a variety of congenital and acquired lesions encountered in open heart surgery, those of the aortic valve are among the most difficult.

2. Advances in techniques of open heart surgery have permitted a direct vision attack for correction of aortic insufficiency.

3. Available surgical methods for dealing with this problem are mentioned.

4. It is apparent that the choice of surgical procedure employed will be largely modified by the pathologic anatomy producing the aortic insufficiency, such as (1) annular dilatation, (2) cusp prolapse, (3) cusp shortening, (4) cusp fenestration, (5) cusp laceration.

5. Several original techniques for inserting partial and total aortic valve substitutes in the supracoronary and subcoronary positions are described.

CLASSIFICATION

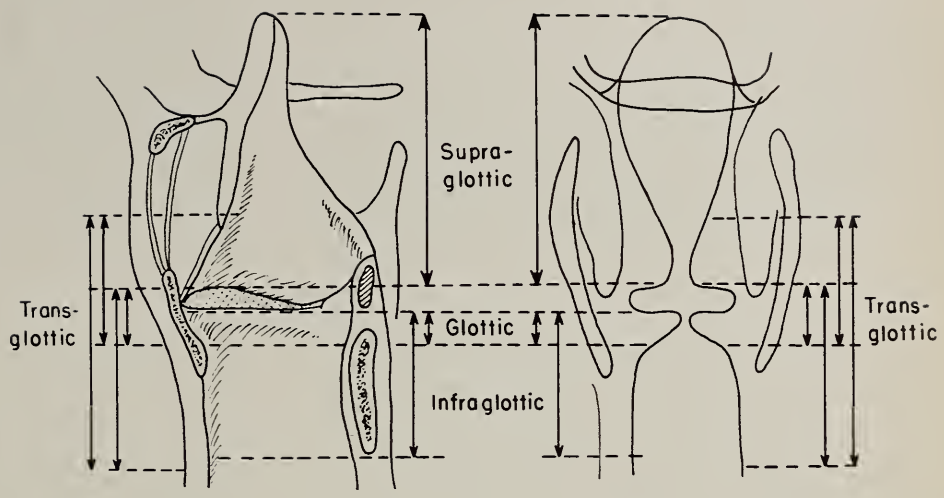

Fig. 1.

Cancer of the Throat

JOSEPH H. OGURA, M.D.
St. Louis, Missouri

Presented at the annual meeting of the Minnesota State Medical Association, May 24, 1960.

TO THE AVERAGE practitioner in medicine, a primary malignant lesion in the anatomic area of the throat has been difficult to visualize and requires the use of special instruments or other visual aids. Unless symptoms are obstructive or painful, usual complaints arising from tumors in this area of the lower pharynx, upper esophagus and larynx are vague. It is distressing that symptoms often are allowed to remain for months and late appearance of palpable masses in the lateral neck then directs the attention of the physician to the primary location.

Once the disease is suspected and confirmed there has been an aura of hopelessness attached to eventual outcome from treatment of such tumors in these locations with a distinct separation between palliation irradiation and radical removal of the larynx. Except for small lesions of the true cord where conservation and a socially acceptable operative procedure can be performed with a high cure rate, present day trends have been towards increasing radical operation methods. Radiation therapy for lesions of the pharynx and esophagus has yielded fair results for cure in the hands of the experienced radiotherapist. For others, palliation is the usual result.

It has only been relatively recent that for extensive lesions of the larynx and pharynx surgical

TABLE I. TREATMENT OF LARYNGEAL CANCER

Intrinsic (glottic, stage I)	Irradiation Laryngofissure Hemilaryngectomy
Endolaryngeal (glottic, stage II, III)	Laryngectomy and neck dissection
Subglottic (subglottis stage II, III)	Laryngectomy and neck dissection
Extrinsic with cordal or arytenoid involvement (supraglottic or laryngopharyngeal stage II, III)	Laryngectomy and neck dissection
Postcricoid or pyriform sinus extension into esophagus	Laryngo-pharyngo-esophagectomy and neck dissection
Epiglottic without cordal invasion (supraglottic cancer stage II, III)	Supraglottic subtotal laryngectomy and neck dissection
Epiglottic without cordal invasion: base of tongue invaded (supraglottic cancer stage II, III)	Extended supraglottic subtotal laryngectomy and neck dissection
Pyriform sinus without cordal-arytenoid involvement, or posterior hypopharyngeal wall (laryngopharyngeal or hypopharyngeal cancer)	Trans-hyoid partial laryngo-pharyngectomy and neck dissection

treatment has been either laryngectomy or combined with extended pharyngeal surgery. When tumor occurs between the larynx and pharynx, many surgeons prefer to remove the larynx in order to remove a tumor of the pharynx, even though the larynx is minimally or questionably involved. The problems of reconstruction and restitution of function are great and it has been easier to remove the larynx than to conserve function.

The purpose of presenting this paper is to bring to your attention some newer techniques and methods of approaches for the treatment of cancer of the pharynx and larynx and esophagus. It is the author's opinion that preservation of "normal" speech and swallow can be maintained in many cancers of this area. Formerly, laryngectomy and neck dissection would have been the treatment of choice, but accuracy of localization leaves a sharp distinction between radical destructive surgery and a conservative operation that is just as radical.

Pathology

In over 95 per cent of the lesions of the pharynx and larynx the tumor is squamous cell cancer. The incidence of nodal metastases from such a lesion varies according to location. Recently we have published our observations of nodal metastases associated with certain primary characteristics of cancer of the larynx. I shall summarize the finding of ninety-six consecutive cases of cancer of the larynx confirmed between 1950 and 1959. We classified the lesions according to (1) Glottic cancers limited to the true cord, (2) Infraglottic cancers of the subglottis and glottis, (3) Supraglottic cancers involving the false cord, fixed cord and free portion, (4) Transglottic cancers across the ventricle thus involving two or three of the other sites. The rare ventricle tumors are included in this group (Fig. 1).

There was a progressive increase in metastatic rate from glottic, infraglottic, supraglottic and transglottic—0, 19, 33 and 52 per cent respectively. The metastatic rate of the transglottic group represents the addition of the infraglottic and supraglottic, confirming the expected results derived from the theoretical considerations of the lymphatic drainage of the larynx. The transglottic group yielded a higher incidence of clinical apparent and inapparent metastases. The metastatic rate for the inapparent metastases for the infraglottic group was 22 per cent, the supraglottic 4 per cent and the transglottic 31 per cent. Supraglottic and infraglottic cancers larger than 2 cms. of moderate or poor differentiation constitute a high incidence of metastases. Cancers of these two locations that are well differentiated of any size; those of 2 cms. or less and moderately or poorly differentiated provide a poor yield of metastases. Of twenty-three patients with supraglottic or transglottic cancers, those who have cervical metastases initially, eleven (48 per cent) had proved positive nodes in the contra-lateral side of the neck on follow up surgery. Consideration in these cases should be given to bilateral neck dissection (one or two stage). Supraglottic tumors appear to be the pushing type rather than infiltrating, particularly when they are well differentiated.

Those cases of laryngeal cancer can be separated into groups with low or high metastatic rate by using pre-operative information about site, size, biopsy, differentiation, and clinical evaluation of cervical nodes. The pyriform sinus and posterior wall of the pharynx are known for their high incidence of cervical metastases. They are usually of moderate or poor differentiation and the tumors are usually two centimeters or larger.

TABLE II. LARYNGECTOMY AND NECK DISSECTION CONSECUTIVE PATIENTS TREATED BY ONE STAGE SURGERY
(Five year results of fifty-nine patients operative mortality three per cent)

	Endolaryngeal	Subglottic	Extrinsic
Total cases	18	13	28
Postoperative death	1	1	0
5-12 years	10/17-59%	7/12-59%	9/28-32%
No follow-up	1	1	3
Elective neck series	9/13-69%	7/12-59%	5/14-36%

Symptomatology

Except for a tumor that arises from the true cord where hoarseness is manifest early, tumors of the epiglottis and pyriform sinus do not exhibit many symptoms until they are large. Often the enlarged palpable node is the first indication that something is wrong with the patient. Cancers of the base of the tongue and vallecula are occasionally silent. Many of the complaints can be grouped under the loose diagnosis of "globus hystericus," a lump in the throat, scratchy sensation in the throat, a sensation of irritation, changes in drinking habits, that is, preference for warm beer rather than cold beer. Such complaints may be overlooked by the physician unless one looks at the parynx by indirect or direct means. Pain referred to the ear is a frequent complaint of a lesion in this area. Dysphagia is manifest when a tumor involves the esophagus, and dyspnea when the tumor is so bulky as to restrict the airway.

Diagnosis

It is of utmost importance that size and extent of tumor be accurately noted since treatment depends to a great extent upon an accurate evaluation. Clinical estimation of extent is fraught with many errors. While a rough estimate can be made as to size, we have recently demonstrated that the laryngogram is extremely accurate in localizing the tumor. For example, by laryngogram the accuracy of localizing ninety-nine such lesions both as to size and extent and neighborhood structures was 92 per cent compared to 78 per cent by indirect and direct examination. Direct laryngoscopy and esophagoscopy with biopsy is necessary to establish the true nature of the disease.

Treatment

After the biopsy has been made and we are dealing with squamous cell cancer, the following has been our recommended treatment. If one refers to the Table I little discussion will concern the treatment of glottic cancer restricted to one cord. In our hands small glottic cancers have been very successfully treated by irradiation (92 per cent five year cure rate). I would hesitate to recommend radiation therapy when a skilled radiotherapist is not available. With lesions involving the cord and subglottis or supraglottic lesion extending to or below the anterior commissure, the only treatment is laryngectomy and neck dissection.

Conservation of laryngeal function operations can be performed in one-third of the laryngeal and pharyngeal cases when they are first seen. In a classic example of the epiglottic lesion, the operation which removes this structure can be extended for those lesions in the anterior pyriform sinus or the base of the tongue in continuity with neck dissection. For moderate or small lesions of the pyriform sinus, we have routinely resected the pyriform sinus together with the thyroid cartilage and arytenoid with reconstruction of the pharynx. One leaves only a flaccid true cord which is now paralysed by removal of the arytenoid. The pharynx is reconstructed with or without a skin graft, and with or without a stent. Lesions involving the entire posterior wall may also be resected and reconstructed with a large split thickness graft without sacrificing the larynx. No attempt is made to compromise function at the expense of leaving tumor. The selection of cases has been based purely on location and extent of removal which often includes parts of the larynx. This has been determined by laryngogram and direct laryngoscopy. It is surprising how much of the entire supraglottic area of the larynx may be removed and the patient is still able to speak and swallow. The portion of the larynx that may be left in the most extensive resection consistent with conservation of function is the lower half of the thyroid cartilage, one functioning true vocal cord and one arytenoid. With only this as protective mechanism, the patients are able to swallow and speak with slight difficulty. Occasionally on the very extensive resections when the larynx has been left there is a compromise as to the quality of the food the patient can eat, for example, when the opening of the esophagus is resected some of

the patients can only swallow soft foods and have to wash down large particles of meat with fluids. When a large area of the posterior pharynx has been resected and grafted with skin, this may also have some side effects such as accummulation of mucus which the patient must clear from the throat.

Results

The results of the elective neck dissection with laryngectomy have yielded an increased five year cure rate over total laryngectomy alone (Table II). Since the development of partial laryngectomies, that is, supraglottic subtotal, or trans-hyoid laryngo-pharyngectomy with neck dissection has only been done during the past six years, it is not possible to discuss five-year results.

There has been a total of forty-two patients in this group. In thirty instances, the epiglottis or base of the tongue have been resected. In twelve, the pyriform sinus or posterior wall section with reconstruction has been done. In only one instance has there been local recurrence and this case was with a tumor in the base of the tongue.

The majority of these cases are extending into their second and third year. To the patient it makes a great deal of difference whether function can be preserved and he can return to his position in society. In another two years one should be able to state whether the cure rate is high enough to warrant this conservation approach. On the whole, local recurrence is rare, contra-lateral metastasis has occurred in 10 per cent, and 50 per cent survival without disease for those beyond two years.

It is difficult to compare results of the method which I have developed to that of Alonso. Alonso has left a permanent pharyngostome requiring secondary reconstruction, while I have done immediate reconstruction in all instances. Furthermore, neck dissection is not routine with Alonso; it has been standard practice for all of our cancers in these locations. In a small series, Alonso reports 30 per cent cure rate in pharynx and hypopharynx lesions. This is quite close to our five-year survivals to total laryngectomy and neck dissection for pyriform cancer. I would reasonably expect that our conservation operation results will parallel or improve on this. Anyone with experience knows that if a case survives past the second year, nearly 80 per cent of these cases have been salvaged and will live to a five-year period.

Read at the Conference on Thrombolytic Agents sponsored by Hematology Study Section of the National Institutes of Health, Chicago, Illinois, April 8 and 9, 1960.

CLINICAL evaluation is our major concern in this paper; however, we accept the necessity of adequate laboratory control to add weight to clinical observations, which aspect has been covered by other authors.[1] We have no meaningful figures to demonstrate the efficacy or lack of efficacy of fibrinolytic agents in occlusive cerebrovascular disease, but we should like to call attention to how we think of strokes due to occlusive cerebrovascular disease and to try to relate this to the potential of fibrinolytic agents in the treatment of these conditions. We classify strokes due to occlusive cerebrovascular disease into three temporal categories depending on the state of the patient and his neurologic deficit at the time he is observed by the physician.

Classification of Strokes

Incipient or Impending Stroke.—The first category, the incipient or impending stroke, is represented by episodes of intermittent insufficiency or intermittent focal cerebral ischemia. Between the episodes the patient is normal or nearly normal. These episodes may last a few minutes or, at the most, an hour or so, and they may occur intermittently over several months before a catastrophic episode occurs. They may occur in the distribution of the carotid arterial system or in the vertebral-basilar arterial system.

Advancing Stroke.—The second category is the advancing stroke (slow stroke or stroke in evolution) in which the physician is able to determine that the patient's neurologic deficit is increasing during his observation. This progressive infarction also may occur in either the carotid or the vertebral-basilar system.

Completed Stroke.—The third category is the completed stroke which may occur in either the carotid or vertebral-basilar arterial system. In this

category the neurologic deficit is no longer progressing but is stable. Spontaneous improvement may occur without treatment; in fact, it is to be expected.

These three categories are demonstrated graphically in the accompanying figure.

Treatment

In the incipient stroke, that is, in patients having intermittent episodes of focal cerebral ischemia, the presumption is that the basic pathologic process is atherosclerotic narrowing of an artery with some associated clotting defect; and perhaps at times, hypotension, polycythemia, anemia, or other factors play a role.

Patients having incipient strokes have been treated with anticoagulants with apparent success;[2] recently, in selected cases, surgical correction of stenosed arteries has proved successful.[3] Fibrinolytic agents would seem to be of little value in this category since more than short-term administration of treatment is needed and, at this time, prolonged use of these agents does not seem reasonable and may even be harmful.

Advancing strokes may offer an area for more potential gain from fibrinolytic therapy. Time is the important factor in treatment for such progressing infarction. A few hours, or often less time, may allow severe and irreversible infarction to occur. One is unable to procrastinate if any treatment is going to be effective. Anticoagulants[4] have been helpful in treatment of advancing strokes, but there is room for improvement of treatment, judging from our experience so far.

The time required for lysis of an arterial clot by fibrinolytic agents administered intravenously is probably too long for optimal benefit in cases of advancing stroke. Direct injection of a fibrinolytic substance into an occluded artery may be more desirable and may yield more certain lysis of an intra-arterial thrombus.

Most, if not all, reported cases in which fibrinolytic agents had been used in treatment were those of patients having completed strokes. Unfortunately in such instances, the infarction is established and elimination of the occlusion is not likely to alter the established infarct.

At necropsy Yates[5] studied the entire carotid and vertebral arterial systems of 100 patients who had manifested some clinical evidence of cerebral ischemia. He found seventy-four cerebral infarcts in thirty-five cases, and only twenty-two of these infarcts could be accounted for by occlusion or even by stenosis of an appropriate local artery. In the 100 necropsies he found occlusion or greater than 50 per cent stenosis in fifty-seven vertebral arteries and seventy-seven carotid arteries. The important point, however, is that in this whole group he found thrombosis as a part of occlusion or stenosis in only six vertebral arteries and fifteen carotid arteries; in all other cases occlusion or stenosis was due to atherosclerosis. This demonstrates the limitations with which we are dealing in a particular instance of cerebral ischemia.

TABLE I. NATURAL HISTORY: OUTCOME OF UNTREATED CEREBRAL INFARCTION IN CAROTID SYSTEM[7]

Status	Patients	
	Number	Per Cent
Asymptomatic	25	12
Able to work (monoparesis or hemiparesis, grade 1*)	33	16
Unable to work (hemiparesis, grade 2 or 3*)	76	38
Permanent invalid (hemiparesis, grade 4*)	41	20
Dead	29	14
Total	204	100

*Graded on a basis of one (mild) to four (severest).

Evaluation of Use of Fibrinolytic Agents

Two methods by which we can attempt to evaluate fibrinolytic agents in occlusive cerebrovascular disease, whether we are considering incipient strokes, advancing strokes, or completed strokes, are as follows: (1) by comparison of the patient's clinical course after therapy with the course of a control group, and (2) by arteriographic determination of the flow of blood in arteries related to the cerebral ischemia. We will relate evaluation of fibrinolytic agents to completed strokes since, up to this time, this type of stroke is the only type reported[6] in which fibrinolytic agents have been used. It is not this type, however, which is likely to receive much benefit from these agents.

In evaluation of the patient's clinical course after therapy, we may compare our results with results obtained for control patients or, more simply, with results in our past experience in a particular category. For example, a previous study of the natural history[7] of clinically diagnosed infarction in the carotid arterial system revealed that 12 per cent of the patients become asymptomatic, 14 per cent of the patients die, 20 per cent are permanent invalids and 16 per cent have only a mild neurologic

deficit (Table I). Thirty-eight per cent of the patients are in between these categories. From these findings, one can readily see that drawing conclusions purely from clinical observation in a single instance or in a few instances will not shed much light on this problem. The course is too variable.

Secondly we may evaluate the flow of blood by arteriographic means and demonstrate when an artery is occluded after a cerebral ischemic episode. It is necessary, however, to be cautious in declaring that intracranial arteries are occluded when they do not fill with contrast media, particularly when they are viewed after a single injection. When fibrinolytic treatment is used, if it is effective, another arteriogram should show that the arterial occlusion has been eliminated. We would reiterate, however, that in cases of completed infarction little or nothing can be accomplished, in so far as neurologic deficit is concerned, by elimination of the occlusion. If the neurologic deficit is mild after a completed infarct, and if it is possible to eliminate the occlusion and maintain patency of the vessel, protection of the patient from additional trouble later may have been accomplished. In such instances, treatment with fibrinolytic agents may offer an advantage over current surgical treatment since it could also be directed toward intracranial thrombotic occlusions.

One must be cautious in assuming lysis of an embolic clot fragment as determined by an arteriogram made subsequent to treatment since it is not uncommon for embolic fragments to move or for lysis to occur spontaneously.

We have tried the arteriographic approach to evaluation of therapy in a few cases with intravenous infusion of 50,000 to 100,000 units of plasmin (Actase*) over a period of two to three hours. In most instances, the preparation was given on two successive days. Thus far we have not been successful in demonstrating lysis of an intra-arterial clot by such an intravenous infusion.

By way of example, we had a patient who experienced a sudden onset of hemiplegia and aphasia on the right side. An arteriogram demonstrated occlusion of the left internal carotid artery. Infusion of plasmin was started soon after the arteriogram was completed. Complications, that is, chills and fever and a drop in blood pressure some hours later, developed owing to the infusion. We were unable to demonstrate a significant change in the prothrombin time, concentration of fibrinogen in the plasma, or time required for lysis of an euglobulin clot in comparing blood obtained prior to and immediately after the infusion. The patient died after the second day of treatment, but his death probably was not related to the infusion since he had a rather massive cerebral infarct. Necropsy revealed a fresh thrombus still in place in the internal carotid artery which indicated that the intravenous infusion in this instance did not alter the internal carotid thrombosis.

*Our supply of actase was obtained through the courtesy of the Ortho Pharmaceutical Corporation, Raritan, New Jersey.

Summary

When the treatment of occlusive cerebrovascular disease with fibrinolytic agents is considered, it is imperative to keep in mind the limitations of ischemia in the end-organ, that is, the brain. The following two areas of occlusive cerebrovascular disease deserve thorough study in regard to treatment with fibrinolytic agents: (1) advancing or progressing infarction due to thrombosis which may be altered if lysis can be accomplished within a short time; and (2) mild neurologic deficit existing after a completed infarct since the patient may be given protection from future additional neurologic deficit if an occlusion related to the infarct can be eliminated.

Aided by a grant from the U. S. Public Health Service.

WHEN a patient with hypertension and renal insufficiency is admitted to the medical service, it is often difficult to determine the basic nature of his illness. If there is glyosuria or a high fasting blood sugar, a diagnosis of intercapillary glomerulosclerosis is indicated. Bilateral polycystic kidneys often may be recognized by palpation or roentgenography. Very rarely this syndrome may be produced by obstructive pyelonephritis complicating benign hypertension. When diabetes has been excluded, 99 per cent of the cases are either chronic glomerulonephritis or malignant hypertension. In this discussion malignant hypertension is defined as primary hypertension with renal insufficiency.

Clinically malignant hypertension and chronic glomerulonephritis are difficult to distinguish after the onset of renal insufficiency, since both are characterized by hypertension and uremia. But when an accurate history is available for a few years preceding the onset of uremia there is usually no difficulty in making the distinction. In malignant hypertension the high blood pressure precedes the onset of uremia while in chronic glomerulonephritis the blood pressure is not elevated until after a demonstrable renal insufficiency has developed. In about one-third of the cases of chronic glomerulonephritis a well-documented history of acute glomerulonephritis is available; but in the remaining two-thirds the acute attack is not recognized. The cardinal signs of acute glomerulonephritis are hematuria, proteinuria, edema, and hypertension. Proteinuria alone constitutes insufficient evidence of glomerulonephritis. Often the available clinical history is not sufficient for a differential diagnosis.

In this study, the diagnosis is based in every case upon the microscopic structure of the kidneys. Malignant hypertension is an occlusive disease of the renal arteries with secondary atrophy of the glomeruli and tubules. There is a fibro-elastic intimal thickening of the medium-sized and small arteries (Fig. 1). The arteries show a massive thickening of the intima with replacement of most of the muscular media. The concentric rings of elastic and collagenous fibers reduce the lumen to a small opening and produce the so-called "onion-skin" appearance. This intimal thickening affects the small arteries but not the afferent arterioles.

The terminal arterioles frequently show thrombosis of the lumen with necrosis of the wall of the arteriole. This is called thrombonecrosis. It occurs only in malignant hypertension and is usually associated with a sharp decrease of renal func-

tion. The necrosis sometimes extends from the arteriole into the glomerulus.

When the kidney of malignant hypertension is examined under low magnification (Fig. 2) the most impressive feature is the thick-walled arteries. Because of the ischemia most of the glomeruli are hyalinized and the tubules are atrophic.

Conversely, in chronic glomerulonephritis (Fig. 3), the small arteries are inconspicuous. One sees many hyaline glomeruli and other glomeruli whose capillaries are only partly occluded. This is a primary disease of the glomeruli with secondary tubular atrophy. The arteries and arterioles are not involved.

In both malignant hypertension and chronic glomerulonephritis, many hyaline glomeruli and atrophic tubules are noted. The problem for the pathologist is determining whether the cortical atrophy is due to primary disease of the glomeruli or primary occlusion of the small arteries. The distinction can usually be made without difficulty.

This study is based upon the clinical records and necropsy material of 708 cases of malignant hypertension and 368 cases of chronic glomerulonephritis. It includes every case of each group in the necropsy records of the Department of Pathology at University of Minnesota Hospitals from 1918 through 1957. The chief purpose of the study is to establish clinical distinctions between these two diseases.

TABLE V. A COMPARISON OF THE COMBINED WEIGHT OF THE KIDNEYS IN MALIGNANT HYPERTENSION AND CHRONIC GLOMERULONEPHRITIS

Weight of Kidneys (Grams)	Number of Cases			Per Cent Due To	
	Malignant Hypertension	Chronic Glomerulon.	Total	Malignant Hypertension	Chronic Glomerulon.
50 to 100	26	45	71	36.6	63.4
100 to 150	99	74	173	57.2	42.8
150 to 200	140	61	201	69.6	30.4
200 to 300	291	95	386	75.4	24.6
300 to 400	116	48	164	70.7	29.3
400 to 500	30	31	61	49.2	50.8
500+	2	11	13	15.4	84.6
Total	704	365	1069		

Type of Onset.—It was noted above that in malignant hypertension the high blood pressure precedes the onset of renal insufficiency while in chronic glomerulonephritis the reverse relation obtains.

Age (Table I).—In persons under 30 years of age it appears that about 85 per cent of the cases are glomerulonephritis, but after that age malignant hypertension preponderates greatly. After

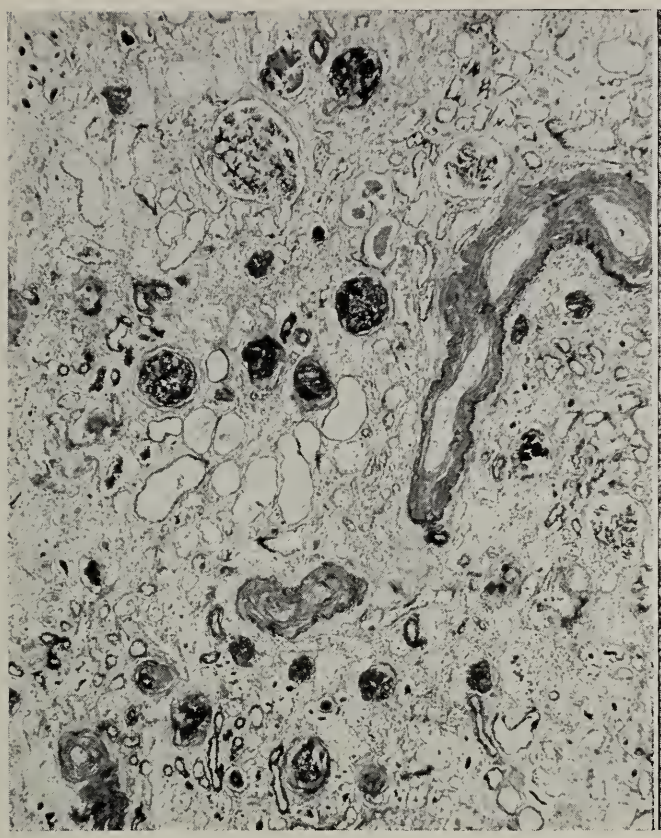

Fig. 2. Kidney from a case of malignant hypertension. Low magnification. Note thick-walled arteries, hyaline glomeruli and atrophic tubules. There are a few normal glomeruli.

Fig. 3. Kidney from a case of chronic glomerulonephritis. The arteries are inconspicuous. Many glomeruli are obliterated, but a majority are only partially occluded and are connected to tubules that are decreased in size because of the reduced glomerular filtration.

the age of forty years hypertension is four times as frequent and after sixty years—six times as frequent as glomerulonephritis.

TABLE II. DURATION OF SYMPTOMS

Duration of Symptoms	Malignant Hypertension		Chronic Glomerulonephritis	
	Number of Cases	Per Cent of Total	Number of Cases	Per Cent of Total

Sex (Table I).—In the necropsies there are about twice as many males as females in subjects over twenty-five years of age, so that the number of females should be doubled in comparing sex incidence. When this adjustment is made it appears that there is no sex preponderance in glomerulonephritis; but in malignant hypertension there is a great preponderance of females in the group twenty to forty years old.

Duration of Symptoms (Table II).—The total duration of the disease can seldom be determined accurately. We know when the patient first noticed something abnormal but the disease develops insidiously and is commonly well advanced before a physician is consulted. In about one-third of the cases of chronic glomerulonephritis the onset may be dated by the acute attack; but in the remainder the first symptoms noted by the patient are those referable to renal insufficiency such as anemia, weakness, headache, and dyspnea.

In malignant hypertension the onset is usually dated by symptoms of myocardial failure, coronary disease, headache, apoplexy, or anemia. Often a high blood pressure is found on routine examination of an asymptomatic person. Commonly, hypertension is present many years before the appearance of impressive symptoms. The great majority of persons with malignant hypertension have had "benign" hypertension many years before the

malignant phase develops. Only about 20 per cent of persons with severe primary hypertension, e.g., 180/100 mm. Hg or higher, ever develop renal insufficiency. More commonly they die of myocardial failure, coronary disease, or apoplexy.

The duration of symptoms shown in Table II is, of course, not a true measure of the duration of the high blood pressure, especially in cases of short duration. The table shows only the duration of impressive symptoms. It is noteworthy that fifteen subjects were known to have had hypertension for over twenty years. Duration of symptoms is not helpful in distinguishing malignant hypertension from chronic glomerulonephritis.

Proteinuria.—The routine urine examination during the last hospital admission of 558 patients with malignant hypertension showed proteinuria: 0 or a trace in 11.5 per cent; 1+ or 2+ in 48.2 per cent; and 3+ or 4+ in 40.3 per cent. In 328 cases of chronic glomerulonephritis the urine showed protein: 0 or a trace in 4.3 per cent; 1+ or 2+ in 36.6 per cent; and 3+ or 4+ in 59.1 per cent. Proteinuria is usually more pronounced in glomerulonephritis especially in cases of subacute type; but the difference is not enough to be of diagnostic value. There may even be hematuria in acute fulminating malignant hypertension. Proteinuria in an otherwise asymptomatic individual does not establish a diagnosis of glomerulonephritis.

Edema.—In 668 cases of malignant hypertension, peripheral edema was absent at all times in 52.2 per cent, moderate in 37.1 per cent, and severe in 10.6 per cent. In this disease edema is due to right heart failure.

In 376 cases of chronic glomerulonephritis there was no edema at any time in 41.5 per cent; moderate edema in 40.2 per cent, and severe edema in 18.3 per cent. The edema in this disease is due to low plasma albumin resulting from proteinuria and malnutrition. Occasionally myocardial failure is a contributory factor. Edema has some value in the differential diagnosis if its cause can be established.

The Blood Pressure (Table III).—The cases are grouped in Table III with respect to the maximum blood pressure. The pressure may be low early in the disease or it may fall terminally as a result of cardiac failure. The systolic pressure is cited since the diastolic usually corresponds with it; but a diastolic of 100 mm. Hg or more is considered hypertensive even when the systolic pressure is below 150 mm. Hg.

There are twenty cases of malignant hypertension in which the systolic pressure was below 150 mm. Hg and the diastolic below 90 mm. Hg. All of these had the typical kidneys of malignant hypertension microscopically. In ten of these the heart was very large indicating that the low pressure was due to cardiac failure in a previously hypertensive subject. In the other ten cases the hearts were of normal size and we cannot prove that these subjects were ever hypertensive.

About 80 per cent of persons with malignant hypertension exhibit systolic pressures of 200 mm. Hg or higher, while only 30 per cent of those with glomerulonephritis have such pressures. It also appears that 77.8 per cent of patients with a systolic pressure of 200 to 239 mm. Hg, and 93.2 per cent of those with 240 mm. Hg or higher have malignant hypertension. On the other hand, about 80 per cent of patients with uremia and a systolic pressure below 180 mm. Hg are examples of glomerulonephritis—other causes of azotemia having been excluded.

It is to be remembered that in malignant hypertension the high blood pressure *precedes* the signs of renal insufficiency, while in glomerulonephritis the elevated pressure is *caused* by renal insufficiency. Commonly persons with malignant hypertension have had a high blood pressure for many years with no evidence of renal involvement other than proteinuria. In chronic glomerulonephritis the blood pressure is only moderately elevated at first but gradually rises to higher levels as renal insufficiency increases. But in malignant hypertension one often finds a gradual rise of blood pressure over several years.

Hemoglobin.—A severe anemia is found in all cases of chronic uremia regardless of etiology. In some cases of malignant hypertension with acute uremia the hemoglobin is only moderately diminished.

Significance of Vascular Disease.—Among 368 cases of chronic glomerulonephritis there were three clinical cases of coronary disease and three cases of apoplexy—an incidence of 1.6 per cent of vascular disease. Among 708 cases of malignant hypertension there were forty-seven clinical cases of coronary disease, fifty-one instances of ence-

phalomelacia, and twenty-nine cases of cerebral hemorrhage. If we subtract seven overlapping cases with both apoplexy and coronary disease we have 120 serious vascular lesions. This gives an incidence of 17.2 per cent vascular disease in malignant hypertension as compared with 1.6 per cent in chronic glomerulonephritis. If a patient with hypertension and uremia gives a history of coronary disease or apoplexy, malignant hypertension is highly probable.

Hypertensive Retinopathy.—Hypertensive retinopathy is used to include eyegrounds with hemorrhages and exudates (grade 3), as well as those with papilledema. The data on this topic are wholly inadequate since the eyegrounds were examined in only about one-half of the patients. Presumably retinopathy was less frequent in those not examined since they did not complain of poor vision. Retinopathy was noted in 92 per cent of 354 subjects with malignant hypertension, and in 75 per cent of 155 patients with glomerulonephritis. There is a direct correlation between the height of the blood pressure and the presence of retinopathy. Subjects with glomerulonephritis and a systolic blood pressure of 200 mm. Hg or higher usually have retinal changes. A few persons with malignant hypertension and very high blood pressure do not have retinal stigmata.

Weight of the Heart (Table IV).—At necropsy the weight of the heart is of some value in the differential diagnosis. In males about two-thirds of the hearts weighing less than 400 gm. are cases of glomerulonephritis; and about 80 per cent of those weighing over 500 gm. and 90 per cent of those weighing over 600 gm. are examples of malignant hypertension.

In female patients, about 70 per cent of the hearts weighing less than 400 gm. are examples of glomerulonephritis, and about 90 per cent of those weighing over 500 gm. are cases of malignant hypertension.

Weight of the Kidneys (Table V).—The combined weight of the kidneys is shown in Table V. The kidneys were severely contracted (50 to 150 gm.) in 17.6 per cent of the malignant hypertensive subjects and in about 33 per cent of those with glomerulonephritis. Some degree of shrinkage (less than 300 gm.) was present in about three-fourths of each group. A majority of the large kidneys are examples of chronic glomerulonephritis in which shrinkage had not developed. The size of the kidneys is not helpful in the differential diagnosis; but if one finds hard rigid arteries entering the kidney, a diagnosis of malignant hypertension is indicated.

Summary

Among 1,076 subjects dead of uremia associated with hypertension, there were 706 cases of malignant hypertension and 368 cases of chronic glomerulonephritis. The differentiation between these two diseases was made by histologic study of the kidneys.

When a complete clinical history is available, the differential diagnosis is not difficult, since in malignant hypertension the high blood pressure precedes the renal insufficiency while in chronic glomerulonephritis the reverse obtains.

When the clinical history is inadequate, the following points are useful in the differential diagnosis:

In about one-third of the cases of chronic glomerulonephritis a well-documented history of an acute attack establishes the diagnosis. A history of proteinuria without edema is not sufficient evidence of acute glomerulonephritis.

About 85 per cent of subjects under thirty years of age with hypertension and uremia have glomerulonephritis. After the age of forty years malignant hypertension is four times more frequent and after sixty years six times more frequent than glomerulonephritis.

In the group twenty to forty years of age, there is a great preponderance of malignant hypertension in females.

The duration of symptoms is not helpful in distinguishing malignant hypertension from chronic glomerulonephritis.

Only about 20 per cent of persons with severe benign hypertension ever develop the malignant phase.

About 80 per cent of persons with malignant hypertension exhibit pressures of 200 mm. Hg or higher, while only 30 per cent of those with chronic glomerulonephritis exhibit such pressures. Over 90 per cent of those with systolic pressures of 240 mm. Hg or higher have malignant hypertension.

Retinopathy is not a distinctive feature since it is related to the height of the blood pressure and not to its cause.

Traumatic Shock

S. R. MAXEINER, JR., M.D.
Minneapolis, Minnesota

SHOCK is defined as a state of persistent deficiency of blood flow with inadequate perfusion of all the body tissues. Intrinsic within this statement is the realization that this state of shock causes tissue damage, which in turn increases the shock picture. This leads to the truism that shock promotes shock. There is a diminished circulating blood volume, diminished arterial blood pressure, and diminished cardiac output. Peripherally there is a marked arterial vasoconstriction. These factors produce a marked decrease in the perfusion of tissues with oxygen and nutrients and an accumulation within the tissues of various metabolites.

Pathologic Physiology

The *heart* usually beats at an increased rate, allowing a shorter time for diastolic filling of the coronary bed. Diminished perfusion pressure at the coronary ostia also contributes to decreased coronary circulation. In the presence of atheromas of the coronary vessels, this diminution of the coronary circulation becomes especially critical.

In the *lungs,* diminished perfusion produces carbon dioxide retention, with a respiratory acidosis which contributes to poor cardiac action and potentiates the shock picture. Late in the shock syndrome actual hypoxia from poor pulmonary circulation results.

In the *kidneys* a particularly early and severe arterial vasoconstriction occurs, with diminution and cessation of renal function. The early effects of this change are accumulation of nitrogenous products, and the loss of renal actions on acid-base balance. Should these conditions persist, destructive lesions of the tubules occur, with acute renal insufficiency as a result.

In the *liver* the diminished perfusion secondary to shock produces failure of the detoxifying actions with an accumulation of pigments, toxins and metabolites in the system, which products further contribute to the formation of shock.

The *blood vessels* themselves, by virtue of diminished perfusion, lose their ability to constrict, producing a loss of peripheral resistance and an increase in the shock picture. All tissues of the body subjected to inadequate perfusion are unable to perform normal metabolic functions, with a resulting hypoxic acidosis. The interruption of energy metabolism yields an elevation of pyruvic acid, lactic acid, and amino acids, and a shift of potassium out of the cells. These changes promote cardiac arrhythmias and failure, as well as shock.

Where sepsis is a part of the clinical picture, inadequate perfusion of the tissues impairs body defenses and promotes sepsis, with further aggravation of the shock picture.

An iatrogenic effect should also be noted, namely the effect of citrate. Hypovolemic shock calls for the administration of large volumes of citrated human blood. Under the situations of shock, the citrate is not oxidized as it is in the normal patient, and has two effects: ionized calcium is bound, producing hypocalcemia; and acidosis is magnified. Hypocalcemia and acidosis potentiate cardiac difficulties and promote the shock picture.

In summary, some of the metabolic effects of shock are: metabolic acidosis, respiratory acidosis, hyponatremia, hypocalcemia, hyperkalemia, and hypermagnesemia. These changes reduce the effects of epinephrine and norepinephrine on the contraction of peripheral vessels and on the rate and contraction of the heart. They reduce the effect of digitalis on the heart. They reduce the efficiency of myocardial contractions. These effects arise from inadequate tissue perfusion, and immediately reduce tissue perfusion, progressively deepening shock. The therapeutic conclusions are that shock promotes shock and that, *to be successful, reversal of the shock picture must be accomplished as rapidly as possible.*

Hypovolemia of Shock

Traumatic shock is almost always a hypovolemic shock, with the blood volume lost in one of the five following ways.

1. By arterial hemorrhage, as in bleeding ulcer, ectopic pregnancy, ruptured spleen, or vascular trauma. Arterial hemorrhage is characterized by a sudden loss of peripheral resistance with a resultant precipitous drop in arterial blood pressure.

2. By capillary and venous hemorrhage, as in fractures and soft tissue trauma. The major part of the blood loss in these conditions comes from

Presented at Methodist Hospital, St. Louis Park (Minneapolis), Minnesota, Symposium on Automobile Trauma, November 14, 1959.

the side of the circulation distal to compensatory vasoconstrictive reactions. Consequently, arterial blood pressure is better maintained and the shock picture develops more slowly.

3. By interstitial losses of blood and plasma as in hemorrhagic pancreatitis, fractures, and soft tissue trauma of extensive nature.

4. By interstitial losses of plasma as in burns, peritonitis, and wound sepsis.

5. By losses of water and salt as in diarrhea, vomiting, fistulous drainage, intestinal obstruction.

For the sake of completeness we should mention normovolemic shock which includes the following mechanisms:

1. Cardiogenic, as in coronary occlusion, cardiac tamponade, and hypervagotonic conditions.

2. Endocrinogenic: adrenal cortical insufficiency, either with true Addison's disease or with adrenal cortical suppression secondary to medication; also adrenal medullary insufficiency secondary to surgical removal of the adrenals or of a functioning pheochromocytoma.

3. Anaphylactic.

4. Septic especially with Gram-negative bacteremia.

5. Neurologic, secondary to traumatic or other lesion of the central nervous system. These latter three mechanisms apparently work by loss of peripheral resistance without primary effects on blood volume.

Faced with the patient in traumatic shock, which we have described to be usually related to loss of blood volume, we are required to restore blood volume promptly and completely. We must decide how much blood need be replaced. In pure hemorrhage, a rule of thumb may be stated that a healthy patient may lose up to 15 per cent of his blood volume without shock. Moderate shock with a systolic pressure of 70 to 90 mm. of mercury and a pulse of 110 to 130 beats per minute would indicate a loss of blood volume of about 25 per cent. Severe shock with a systolic blood pressure essentially unobtainable, and with oliguria, represents about 30 to 50 per cent loss of blood volume.

As time passes, however, replacement of this much blood volume may be insufficient to resuscitate the patient in traumatic shock. Very large amounts of blood and plasma may be sequestrated in the damaged tissue. Several hours following the traumatic episode with extensive tissue damage another 50 per cent of blood volume may be sequestrated and physiologically lost to the patient. With massive soft tissue trauma even 100 per cent of blood volume may become so sequestrated. This is the explanation for the massive requirements of blood and blood substitutes to resuscitate the patient suffering from severe traumatic shock. The requirement for adequate resuscitation may far exceed the actual blood lost as hemorrhage.

Should surgery become necessary in the early treatment of the shock patient, anesthesia may affect the circulation by promoting vasodilation, decreasing peripheral resistance and dropping the blood pressure again. Consequently, more blood volume may be necessary for the patient to withstand anesthesia. Attending surgical blood losses must also be replaced. Considering all these factors, it is obvious that very large amounts of blood may be necessary even up to three blood volumes of the patient in question.

It is Moore's[1] suggestion that these volumes of blood be given rapidly and fearlessly to the patient in shock, including old people in whom coronary disease may be present. He states that it is far preferable to accept the risk of over-transfusion rather than to accept the risk of inadequate resuscitation. Over-transfusion will be signaled by a rise in venous pressure as the heart begins to fail. In most circumstances, the heart will be able to absorb the blood from the venous side and pump it out on the arterial side to restore adequate blood pressure. However with diminished coronary perfusion pressure, particularly in the presence of coronary sclerosis, the heart may be too severely handicapped in the shock state to pump blood from the venous side sufficiently well to restore arterial blood pressure. Should cardiac failure, with elevation of venous pressure, occur before the restoration of arterial blood pressure, then digitalization and intraarterial transfusion are indicated. The function of intraarterial transfusion is to elevate the arterial blood pressure for several minutes, and allow the blood coming from the left ventricle to perfuse the coronary tree at an elevated arterial pressure, in the hope that myocardial function will be sufficiently improved to allow the heart to maintain adequate circulation from this point on.

We may estimate our resuscitative requirements then as units of blood volume for the patient at hand. This figure must be translated into cubic centimeters, and our conversion factor is calculated as follows. For women, 6.5 per cent of

actual body weight is a good approximation of the blood volume. In the case of men, 7 per cent of body weight applies. Obesity shifts the figure to the lower side, and heavy musculature makes this percentage somewhat higher. Plasma volume is estimated at 4 per cent of actual body weight.

Plan of Therapy

We are now ready to outline a plan of initial treatment of the traumatized patient in severe shock. The most urgent initial steps are to establish a free airway, to control hemorrhage, and to evaluate central nervous system injury. The next step is to start intravenous fluids, which almost certainly will be required unless the patient has either brain damage or crushing injury to the chest which may promote a wet lung. With these steps underway and while blood is being made available, complete examination must be performed. The purpose of this examination is threefold: to identify all injuries which have occurred, to establish a base line of physical findings for future examination as further evidences of injury may develop, and to identify any pre-existing diseases which may affect the patient's physiology. An indwelling urethral catheter should be inserted for the purposes of identifying possible injury to the urinary tract and of enabling the physician to measure the hourly urine output, a vital measurement in the consideration of the patient in traumatic shock. And finally, the circulating blood volume must be restored. This must be accomplished rapidly and completely, through two or three intravenous portals as necessary, so that the calculated requirement can be infused within sixty to ninety minutes. One gram of calcium gluconate should be administered with each 1000 cc. of bank blood.

There are certain danger signals which must be observed in the shock patient. If the *skin is warm and dry* in the presence of shock, beware of central nervous system injury. *Cyanosis* is not usually present in pure shock. One should beware of airway obstruction, pneumothorax, mediastinal emphysema, flail chest, cardiac tamponade, or ruptured viscus. While the patient's mental state may be depressed, true *coma* should suggest the presence of injury to the central nervous system. A *bradycardia* instead of tachycardia should suggest hypervagotonia, as seen recently in a patient with multiple fractured ribs under observation for possible ruptured spleen. Twelve hours after the injury her blood pressure dropped precipitously and she appeared to be in shock. Surgery for splenectomy seemed indicated, but it was noted that her pulse was only 60. Intravenous atropine relieved all abnormal findings and the patient never required surgery at all. Another danger signal is an *elevated venous pressure*. In ordinary shock, the peripheral veins are collapsed and empty. If the pressure is elevated one should suspect either cardiac failure or cardiac tamponade. Venous pressure can be readily measured by means of a side arm from the transfusion apparatus. *Hyperpyrexia* in the patient in traumatic shock should suggest sepsis or adrenal cortical insufficiency. A general alarm for complete re-evaluation of the patient should be sounded by the *failure of the patient to respond* to adequate transfusion.

Urgent and complete re-evaluation should be accomplished along the following lines. Has the transfusion requirement been accurately estimated or is it in fact inadequate? Is the patient suffering from continuing hemorrhage as from a ruptured spleen or liver? Does the patient have some respiratory inefficiency which can be corrected? Pneumothorax, mediastinal emphysema, or parodoxical motion of the thoracic cage should be again sought for. Is a cardiac lesion contributing to the circulatory inadequacy? The patient may have a myocardial infarction secondary to diminished coronary blood flow, or he may develop cardiac failure, or he may develop a cardiac tamponade. Does the patient have suppressed adrenal function because of previous steroid medication? Does he have an electrolyte imbalance secondary to diarrhea, vomiting, or to low-salt diet for cardiovascular disease? Is there sepsis?

Sepsis may take several forms. It may supervene in the wound which caused the shock, and aggravate fluid losses and toxicity. It may cause the shock by sequestrating large amounts of blood volume in an infected area. This might be particularly true in clostridial infections, and become clinically important as early as six hours after trauma. Or sepsis can produce a direct hypotension with bacteremia by means of diminishing cardiac output and diminishing peripheral resistance.

Good treatment of the patient in traumatic shock requires continual, maximal, careful, enlightened attention by the physician, for whatever time is required to return the patient to well-compensated, stable circulation. Anything less may cost success.

Metabolism of Fructose In Man

ROGER C. MURRAY, M.D.
Saint Paul, Minnesota

KULZ,[1] in 1874, first reported that diabetic patients were able to utilize fructose given orally better than other sugars. Joslin[2] in 1946 stated that in his experiments "at first the fructose was well utilized, but later hyperglycemia and glycosuria usually followed." He found that a diet containing Jerusalem artichokes yielding fructose on digestion could be taken for a period of at least three years without the subject losing his ability to utilize it more efficiently as compared with an equal amount of starch. Minkowski[3] in 1893 observed that fructose in contrast to glucose led to the formation of glycogen in the liver when given to depancreatized dogs. In 1926, Cori[4] demonstrated that the first step in the metabolism of glucose is its phosphorylation to glucose-6-phosphate catalyzed by the enzyme glucokinase only in the presence of insulin. Conversely, he showed that fructose plus A.T.P. (fructokinase) fructose-6-phosphate plus A.D.P. reaction proceeds whether or not insulin is present. Hepatic glycogen is formed much more rapidly from fructose than from glucose, but when stress glycogen formed from fructose is broken down in the liver, it emerges as glucose, not fructose, and insulin is then required to re-incorporate it into the metabolic cycle, as shown in Cori's work. In 1929, Cori[5] studied the utilization of muscle in known amounts of intravenously injected fructose and glucose in eviscerated, depancreatized rats, and subsequently analyzed the entire carcasses for free sugar, finding 39 per cent of the fructose and only 10 per cent of the glucose had disappeared in one hour. The injection of insulin resulted in a marked increase in the rate of disappearance of glucose but had no effect on the metabolism of fructose. In 1950, Slein and Cori[6] showed that separate enzymes existed in muscle for the phosphorylation of fructose and glucose. Insulin apparently acts only with glycokinase. In the liver also a separate enzyme has been identified for the phosphorylation of fructose. In 1951, Chernick and Chaikoff,[7] using a C-14 labeled fructose, found no significant difference in the capacities of normal and diabetic rat livers to oxidize fructose to CO_2.

In 1950, Weichelbaum, Elman, and Lund[8] compared the rates of utilization of intravenously administered 10 per cent glucose and 10 per cent fructose. They found a marked increased speed of assimilation of fructose over glucose as manifested by low blood sugar levels, decreased glycosuria, and decreased water diuresis. They concluded that fructose is a better utilized sugar than glucose for intravenous feeding. In 1951, Craig, Drucker, Miller, Woodward, and co-workers[9] carried on an intensive and systematic study of the metabolism of intravenously administered fructose. Since oral administration of fructose could

not be expected to demonstrate quantitatively, the full effects of fructose because of conversion of at least a portion to glucose by both intestinal mucosa and liver, they gave alternate infusions of glucose and fructose to both normal and diabetic subjects at a rate of 1 gm. of fructose per kilogram, intravenously in a 10 per cent solution, constantly over a period of sixty minutes. The results obtained were compared in the same individual similarly with glucose. The diabetic subjects had had insulin withheld for at least fourteen hours prior to all tests. The fructose and glucose levels were determined separately in both blood and urine, and changes in blood pyruvic acid and serum inorganic phosphorus levels were determined in certain cases as additional indices of carbohydrate metabolism.

Metabolism in Normal Individuals

In normal individuals, this infusion of glucose produced an average blood sugar peak of 253 mg. per cent; the mean excretion of glucose was 6.1 gm. and the average urine volume for three hours after the start of the infusion was 1130 ml. With fructose, however, the average maximum blood glucose was 98 mg. per cent; the average excretion of blood sugar was 4.4 gm. (4.3 gm. fructose and 0.1 gm. glucose), and the average urine volume was 775 ml. There was no renal threshhold for fructose. A slight rise in blood glucose following fructose administration was noted in some instances. That any fructose is excreted is explained by the fact that fructose continues to be excreted even at blood levels as low as 4 mg. per 100 ml. but the smaller rise in blood level minimizes the amount lost in the urine.

This study also showed pyruvic acid levels in the blood rose after glucose infusions, on the average of 28 per cent or 0.30 mg. per 100 ml. above the control level, the peak occurring at sixty minutes. This rise, although small in absolute terms, is significant—the associated probability being of the order of less than 0.5 per cent that so great a difference should arise in random sampling. In contrast, the pyruvate rise after fructose was strikingly higher, averaging 110 per cent or 1.22 mg. per 100 ml. above the level to start. Serum inorganic phosphorus fell after either fructose or glucose, but the difference was in the magnitude in rate of change. After fructose, the phosphorus fall was more rapid than after glucose, reaching its lowest point at thirty minutes and then leveling off at a slightly higher value after ninety minutes.

These results in the normal subject suggest the following conclusions: (1) Fructose is removed from the blood stream more than twice as rapidly as glucose during the period of infusion. (2) The rise in blood glucose following fructose administration indicates that a fraction of the fructose must have been converted to glucose. (3) The rise in pyruvate can be interpreted as an indication that both glucose and fructose are metabolized by the way of the Embden-Meyerhof series of reactions. The much greater rise after fructose is probably a reflection of its entrance into the metabolic scheme closer to pyruvic acid. Hers[10] has shown that in rats fructose is transformed into liver and muscle glycogen by splitting to the triose state and entering the glycolitic scheme just below fructose-1-6-diphosphate. The *in vivo* studies in man are consistent with this hypothesis. If the fall in serum inorganic phosphorus reflects the process of phosphorylation in the metabolism of carbohydrate, the more rapid decrease in phosphate after fructose administration is an indication of the more rapid metabolism or utilization of this sugar.

Metabolism in Diabetic Subjects

Miller and his associates[9] showed that when glucose was infused at the same rate in diabetics from whom insulin had been withdrawn temporarily, the average maximum blood glucose level was 543 mg. per cent, the average glucose excretion was 26.9 gm., and the average urine volume was 731 ml. When fructose was given to the same patients, the mean peak blood glucose level was 337 mg. per cent and the average maximum fructose level was 76 mg. per cent. Although the average total of sugar excretion was only 16.6 gm. (3.7 gm. fructose and 12.9 gm. glucose) the average diuresis was 837 ml. This failure in urine volume to parallel the decrease in total sugar excretion was unexplained. It was noted that in diabetics, fructose disappeared from the blood stream at the same rate as in non-diabetics, since the blood levels of fructose and the amount of fructose excretion were essentially the same in both groups. Most of the total sugar excretion in these diabetics from whom insulin was withheld, was glucose. The metabolism of fructose in the diabetic is similar to that observed in the normal person, but it did differ in that there was a more marked rise in blood glucose following fructose, and this rise was roughly proportionate to the severity of the diabetes.

Approximately 20 per cent of the total amount infused was retained or utilized when fructose was administered. It was interesting to note the disadvantages were independent of the severity of the diabetes.

Another striking difference in the metabolism of glucose and fructose in the diabetic subject was shown by changes in the blood pyruvic acid. After glucose, a significant rise in pyruvate did not occur until ninety minutes, and this rise was sustained even at 180 minutes. In eighteen normal subjects, the maximum rise occurred at sixty minutes or earlier in ten instances, compared with a similar early rise in only one out of the twenty-four experiments in diabetic subjects. Furthermore, in seven of these diabetic patients, no rise was found. In contrast, rise in pyruvate after fructose administration in the diabetic state occurred just as promptly as in the normal subject. The magnitude of this increase was at least as great as in the non-diabetic and was significantly higher from ninety to 180 minutes.

In diabetic subjects, the response of serum inorganic phosphorus through the administration of intravenous glucose and fructose was also markedly different.

After glucose, only a slight fall (statistically not significant) occurred in the first ninety minutes. After fructose there was the same rapid fall, somewhat less in magnitude compared to the normal, in the first thirty minutes with a rise after ninety minutes.

The results in the diabetic subjects in the absence of insulin effect indicate that there is very little impairment in the metabolism of fructose as shown by: (1) essentially similar rate of removal from the blood stream as in the normal person; (2) no reduction in the height of pyruvate rise; and (3) rapid fall in serum inorganic phosphate. In contrast, in parallel circumstances, glucose disappearance from the blood was markedly delayed. The rise in pyruvate is either abolished or delayed in appearance and the phosphate fall is not significant.

Miller et al[9] compared the effects of fructose given by mouth when compared in three individuals with the same amount given intravenously. The fructose was ingested as a 10 per cent solution in water within a few minutes at the beginning of the experiment, while the same amount was given intravenously as a 10 per cent solution in sixty minutes on another occasion. In each instance, after oral administration, the blood fructose level was much lower than that found after intravenous injection, while the elevation of blood glucose was more than twice as great and remained higher for a longer period of time. Part of the fructose, therefore, must have been converted to glucose in its passage through the intestinal mucosa and the liver. In order to compare or determine more directly the amount of conversion of fructose to glucose by the intestinal mucosa, a patient with cirrhosis of the liver and portal obstruction with large superficial and abdominal anastomotic veins was given 50 gm. of fructose by mouth. Femoral artery blood and portal anastomotic vein blood samples were collected simultaneously in thirty and sixty minutes and analyzed for fructose and glucose. If the assumption is made that the utilization of hexose by the intestinal wall is negligble, then the ratio of the increase in the portal anastomotic vein blood glucose to total hexose will be the approximate measure of the conversion of fructose to glucose during the passage through the wall. In the first sample obtained in thirty minutes, the concentration of glucose in the border line anastomotic vein blood was 5 mg. per 100 ml. higher than in the arterial blood reaching the intestine. Since this could have only been derived by conversion from fructose (no other food being given) and the total hexose absorbed in the intestine was 28 mg. per 100 ml., the fraction of fructose converted to glucose during the transfer through the wall was 18 per cent. The results obtained in the second sample were in agreement, so one can say about one-sixth of the fructose in this experiment was converted to glucose during absorption. Consequently, there is less advantage in giving fructose by mouth than by the intravenous route.

The Role of the Liver

The liver plays an important role in carbohydrate metabolism and this is particularly true for fructose. To obtain more direct information in man, hepatic vein catherterizations were performed in diabetic and non-diabetic subjects by Craig and co-workers,[11] splanchnic blood flow being determined by the bromsulfalein technique. Samples of femoral artery and hepatic vein blood were drawn at frequent intervals, and estimates of splanchnic balances of glucose, fructose, and pyruvic acid were calculated by multiplying the approximate arterial-hepatic venous blood concentration difference by the corresponding estimated

splanchnic blood flow. After control samples were collected, 10 per cent fructose or glucose was infused into a peripheral vein at such a rate that one gram of sugar per kilogram of body weight was given in one hour. *Fructose was taken up by the splanchnic system twice as rapidly as was glucose in the non-diabetic subject. This ratio was maintained in the diabetic state in the absence of exogenous insulin effect.* Even in severe diabetic ketosis, the ability of the liver (splanchnic system) to take up fructose remains unimpaired. This more rapid uptake of fructose by the liver is an important factor in the more rapid disappearance of fructose from the blood stream described in the previous section. Studies of pyruvic acid, splanchnic balance in these cases, showed that the normally slow uptake of pyruvic acid was reversed when either glucose or fructose was infused. However, the output was equivalent to only 0.5 per cent of the hexose uptake when glucose was given and to 3.6 per cent when fructose was administered. Consequently, at least part of the greater peripheral concentration of pyruvic acid that occurs when fructose is given is the result of this output by the liver.

Muscle Uptake

The utilization of fructose by muscle tissue has been studied almost entirely in species other than man. Van Itallie[12] in 1953 measured fructose uptake in the forearm (composed of 80 per cent muscle) of ten non-diabetic subjects. After injection of a priming dose of between 25 and 30 gm. of fructose administered intravenously as a 10 per cent solution in approximately a thirty-minute period, the infusion was continued at a constant rate of 0.58 gm. per minute. Capillary and venous bloods were taken at fifteen-minute intervals for one hour beginning thirty to 100 minutes from the start of the experiment and the arterial-venous difference of fructose was determined. At the average arterial level between 66.1 and 68.9 mg. per 100 ml., the A-V difference ranged between 10.6 and 13.4 mg. per 100 ml., even up to two and one-half hours from the beginning of the infusion. Using the same approach, modified so that 30 gm. of fructose was given the first thirty minutes and then continued at 0.58 gm. per minute for two and one-half hours, Miller et al[13] showed a similar uptake of fructose in three experiments on stable diabetic subjects. They showed that at the end of 150 minutes, the A-V difference was more than 7 mg. per 100 ml. In an experiment on another diabetic patient, the arterial level for fructose under these conditions at the end of seventy-five minutes was 30 mg. per 100 ml. and higher than in the vein. Another priming dose was then given, and the rate of infusion was doubled to 1.2 gm. per minute. At the higher arterial levels obtained (225-250 mg. per 100 ml.) the A-V difference immediately increased and at the end of the two and one-half hours was 70 mg. per 100 ml. The magnitude of the amount taken up after such a long period of infusions suggests the conclusion that direct assimilation utilization by muscle cells must have been taking place.

Oxidation in Isotope Studies

Fructose metabolism in man is complicated by the fact that knowledge of its utilization by various tissues is still not sufficiently detailed. Miller et al[14] studied oxidation *in vivo* of C-14 fructose. Ninety microcurie of evenly labeled C-14 fructose without carrier were injected intravenously into normal and diabetic subjects and the specific activity of CO_2 in the expired air was measured at frequent intervals for a period of at least eight hours. These results were then compared with the specific activity of CO_2 in the expired air following the intravenous injection of the same amount of uniformly labeled glucose C-14 in the same normal or diabetic subjects on another occasion. After fructose in the diabetic subject, its peak activity was obtained very rapidly in not more than ten to fifteen minutes and in this instance was even faster than that achieved in the normal subject. In contrast, the peak activity of CO_2 after glucose in the diabetic subject was significantly delayed as compared with the non-diabetic subject. It appears, therefore, that there is a rapid metabolic transport of fructose to the CO_2 pool and that there is no significant reduction in this rate in diabetes even in the absence of insulin. The oxidation of fructose to carbon dioxide does not seem to be under the control of insulin.

Comparison of Glucose and Fructose in Clinical States of Stress

In comparing fructose and glucose in various clinical states associated with disturbances in carbohydrate metabolism (because of the well-documented efforts of stress situations on glucose

metabolism) a series of experiments was performed on non-diabetic human subjects in order to compare the manner in which fructose was handled in the same circumstances by Drucker and his associates.[15] Five patients scheduled for elective herniorrhaphies, under spinal anesthesia and six patients scheduled for *major surgery* (gastrectomy, etc.) under general anesthesia, were given intravenous glucose and fructose (1.0 gm. per kilogram in one hour as a 10 per cent solution) on successive days preoperatively and these were repeated on the first and second postoperative day. All four tolerance tests were done in each patient, the order in which glucose and fructose was given was alternated from case to case. The results of these tolerance tests showed that even the relatively simple trauma of a herniorrhaphy operation was sufficient to elevate the peak value of glucose at the end of the infusion and result in a delayed fall. In the major surgical cases, the lag in the fall of glucose was even more evident (58 mg. per 100 ml. above control values at 180 minutes compared to 34 mg. per 100 ml. in the herniorrhaphy operations). *The fructose tolerance tests, in contrast, were essentially unaltered by the procedure.* A patient with *typhoid fever,* studied during the height of the febrile phase, showed an alteration in glucose tolerance as compared with the test after recovery, while again the fructose tolerance curves were both normal and identical. The mechanisms by which stress situations alter metabolism of glucose are still being vigorously debated. It is possible to speculate with Price[16] that if stress results in the stimulation of the pituitary-adrenal axis (Selye) and the hormones released, inhibit the action of glucokinase resulting in a delay in the entrance of glucose into the metabolic pool, the normal disappearance curves of fructose could then be explained by the fact that fructose has its own separate fructokinase not influenced by these hormones. On the other hand, if insulin acts upon a cellular membrane system to accelerate transport of glucose[17-19] but has no effect on the entrance of fructose into the cell, it must be assumed that the stress must have some inhibitory effect on the factor or factors responsible for glucose transport, but does not affect the permeability of the cell wall to fructose.

General anesthetics, particularly ether, have been reported to elevate the blood sugar and diminish the utilization of carbohydrate.[20] Twelve volunteer subjects were given ether anesthesia without surgery for a period of ninety minutes.[21] Anesthesia was introduced by an intravenous administration of 150 to 300 mg. of thiol pental sodium in order to minimize the excitement and physical activity frequently encountered during the induction, of ether narcosis. Thirty minutes after surgical anesthesia was achieved, a specimen of blood was drawn and 1 mg. per kg. of a 10 per cent solution of glucose (six subjects) or fructose (six subjects) was infused intravenously at a constant rate for one hour, at the end of which time both the infusion and the ether were discontinued. The similar tolerance tests were done as controls in each subject one or more days preceding the anesthesia and twenty-four hours afterwards (three and four subjects in each group respectively). The effect on blood glucose and fructose levels of the first thirty minutes of anesthesia alone was studied in four subjects in each group. The results of those tests showed that ether anesthesia increased the fasting blood glucose significantly from 91 to 130 mg. per 100 ml. but did not alter the fasting blood fructose level. The glucose tolerance test also showed definite impairment during anesthesia but this effect was gone by the next day. There was a slight delay in the return of the blood fructose as compared with the control curve, but this was only a fraction of that seen with glucose (7.5 mg. per 100 ml. compared with 55 mg. per 100 ml. above control values at 180 minutes respectively.)

Starvation diabetes or the induction of impaired carbohydrate tolerance by the restriction of dietary carbohydrate, was first described in 1874 when Lehmann[22] found that the injection of sugar into the mesenteric veins produced greater glycosuria in fasted than in fed dogs. The same alteration in glucose tolerance after deprivation or reduction in carbohydrate intake has been repeatedly shown in man. Peters[23] in his comprehensive review of this problem in 1945, concluded that the available evidence at the time pointed to "defective combustion" as the cause of this impairment. The study of fructose metabolism in states of carbohydrate deprivation was undertaken in man by Miller et al,[9] to determine where the possible sites of the block in combustion might exist. Intravenous glucose tolerance tests were performed on four normal subjects that had previously been on adequate diets. After two days of fasting during which the diets consisted of meat and butter, only the

tolerance tests were repeated. Under similar circumstances, another time fructose tolerance tests were performed on the same four subjects. The rate of removal of the administered fructose was not found to be significantly altered. However, the blood glucose rise associated with the fructose administration is greater after carbohydrate restriction than in the well-fed state, and the return of the blood glucose to initial level was delayed after dietary restriction. These results afford further evidence that the metabolism of fructose differs from the metabolism of glucose in man, and indicate that the block in glucose utilization following carbohydrate deprivation involves one or more of the reactions between glucose and the entry of fructose in the glycolytic scheme. The findings are consistent with the hypothesis of Wyshak and Chaikoff[24] that the glucokinase is impaired by fasting, and the phosphorylation of fructose, which is under the influence of a separate enzyme (fructokinase) is not altered during starvation.

The importance of these observations in the management of clinical diabetes seems clear. The alterations in carbohydrate tolerance in diabetes produced by trauma, infection, or starvation are much more marked than in normal subjects. Since under these circumstances, parenteral fluids are often necessary, the evidence accumulated so far indicates the value of fructose as the carbohydrate of choice in management.

Diabetic Acidosis

Weichelbaum and Daughaday[25] were the first to report on fructose in the treatment of diabetic acidosis. Darragh, Womersley, and Meroney[26] used 2.5 per cent fructose in half normal saline as a primary replacement solution in six diabetic, ketotic patients. Insulin was used in the usual manner. In all six patients, a rapid reduction of blood ketone levels was observed. They also noted a faster decline in the total blood sugar levels in these patients than in those who had received 2.5 per cent glucose in the early hours of treatment.

Dolger and associates[27] demonstrated that fructose offers a unique advantage in the treatment of diabetic acidosis in that it decreases ketone production without aggravating hyperglycemia or glycosuria. They found that in mild ketosis, the administration of 100 gm. of fructose intravenously over a four-hour period was sufficient to abolish ketonuria, even without the use of insulin. At the same time, the hyperglycemia was not appreciably increased and glycosuria actually decreased. Thus, the use of fructose in the initial treatment of diabetic acidosis did not lead to aggravation of hyperglycemia or increased glycosuria, nor to further dehydration or to insulin resistance.

There is considerable evidence to indicate that the patient in acidosis is under stress, either spontaneously or as a result of trauma or infection that may have precipitated the acidosis.[28] A state of insulin resistance exists and insulin accordingly is less effective early in treatment. Field and Stetten[29] have demonstrated the presence of an insulin antagonist in diabetic acidosis, disappearing within hours after treatment is instituted. This antagonist was non-dialyzable and migrated electrophoretically with the alpha-globulin fraction of the serum proteins. Peters[23] has emphasized that the diabetic acidosis is almost invariably associated with carbohydrate starvation and has summarized the evidence for using glucose even in the initial stage. Later, however, Seldin and Tarail[30] reported on seventeen cases of diabetic acidosis receiving moderate or massive injections of glucose early in treatment. They found that hyperglycemia resulted in an increase in the infective osmotic pressure of the extracellular fluid, producing cellular dehydration. The administration of glucose, even though it might replenish glycogen stores and facilitate the combustion of carbohydrate, enhanced the cellular dehydration and perpetuated the polyuria because of the increased excretion of glucose in the urine.

Other authors[31-32] have strongly opposed the use of carbohydrate. Since fructose does not require insulin for its metabolism, it is more rapidly removed from the blood stream, is a better glycogen former than glucose,[33] and its metabolism is not affected by stress states or starvation, its value was assessed in the early treatment of diabetic acidosis under controlled conditions.[34] Miller[9] produced experimental acidosis with the withdrawal of insulin in a human volunteer on three separate occasions. Complete balance studies were done during withdrawal treatment and recovery periods. During insulin withdrawal periods, all exogenous and carbohydrate derived from protein and fat catabolism were excreted almost quantitatively. The period of study covered the first six hours of treatment. The amounts of insulin, water and sodium chloride were similar in each experiment, with hexose as a variable to be investigated. One hundred units of insulin were given initially and 50

units each hour thereafter, for a total of 350 units in a six-hour period in three experiments: (1) 175 gm. of fructose was given, (2) glucose was given in similar amounts and at the same rate, (3) saline alone was given. Solutions were combined in such a way that the total water administered was given at the same rate and amount in each test. When no exogenous carbohydrate was given, the blood glucose fell at an approximate constant rate. After 75 gm. of glucose, there was an initial rise in one hour of approximately 125 gm. per 100 ml. and then a steady fall when the amount of glucose infused was reduced to 20 gm. per hour. After 75 gm. of fructose there was a slight fall in blood glucose at the end of the first hour and then a rapid fall at approximately the same rate as after saline alone. Blood fructose levels were found to be at the same rate as to be expected in normal subjects, the highest level being less than 75 mg. per 100 ml. Carbohydrate balances for the first six hours were as follows: In experiment (1) the administration of 175 gm. of fructose resulted in a net balance of 163 gm.; with glucose administration the net balance was 124 gm.; and with saline alone, the total carbohydrate either stored or utilized measured only 18 gm. The excretion of fructose as such in the urine in experiment (1) amounted to less than 7 gm. Plasma inorganic phosphorus fell least after saline and most after fructose. The administration of carbohydrate did not result in any increased excretion of either sodium or potassium in the urine during treatment. Since potassium was not included in the treatment schedule in the first six hours, serum potassium levels fell, the fall being approximately the same in each instance. After fructose administration there was evidence of some transference of potassium into the cells which was lacking in the other two experiments. *Urinary volume was definitely greater with glucose therapy, but fructose, because of a much smaller excretion of hexose in the urine, caused only slightly greater water output as compared with the control regimen.* Serum ketone levels fell on the average about 25 per cent faster when carbohydrate was administered. No significant difference was found between fructose and glucose in this respect.

Some writers have suggested the recovery from the acidosis would be delayed with fructose therapy because of the markedly increased rate of formation of pyruvic and lactic acid in the blood. Data pertinent to the discussion were obtained in these three experiments on the fourth occasion, when fructose again was used in the treatment under similar controlled conditions. The results show that the use of fructose actually increased the rate of recovery from acidosis, a conclusion that might have been anticipated from the known facts of fructose metabolism. There is no delay in recovery from the acidosis, despite the increased production of pyruvic and lactic acids.

The fundamental goal in the treatment of diabetic acidosis is rapid restoration of normal carbohydrate metabolism. It is imperative to re-establish direct peripheral oxidation of glucose and glycogen storage in the liver as rapidly as possible. The degree to which this can be accomplished will determine the speed from which blood and urinary ketones disappear. It has been shown that this can be affected more rapidly by using glucose from the outset than by using saline alone.[35-38]

However, the improper use of this sugar has certain intrinsic dangers, because glucose, which requires insulin for its utilization, is being given to an insulin deficient patient. This can result in prolonged hyperglycemia, glycosuria, and water diuresis. A sugar which is metabolized normally in the absence of insulin would theoretically be the best carbohydrate to use in the management of diabetic ketosis.

Fructose does not require insulin, either for direct oxidation or for its conversion to glycogen. Independent studies by many investigators confirmed this fact that fructose metabolism precedes at essentially the same rate in normal subjects, in controlled diabetics, and in diabetic acidosis.[37,38] These attributes make fructose superior to glucose in the early treatment of diabetic acidosis, because they result in greater retention and faster utilization of the administered carbohydrate. The rapid utilization of fructose confers upon it several positive advantages over the use of glucose: (1) maximal blood sugar levels are lower, (2) hyperglycemia subsides more rapidly, (3) less total glycosuria occurs, and (4) there ensues more rapid control of polyuria and thus less dehydration of the patient.

In addition, administration of fructose is superior to glucose or the use of saline alone in the management of ketosis since it results in a significantly faster fall in blood ketone levels. Fructose is therefore uniquely fitted for use in initial hours of treatment of diabetic acidosis, since it possesses all the advantages of glucose and none of its dis-

advantages. The advent of fructose renders the old saline *versus* glucose controversy obsolete: according to Seltzer and Conn,[35] higher concentrations of fructose can be used without the danger attending the use of higher concentrations of glucose.

Summary

The metabolism of fructose in normal and diabetic subjects has been reviewed:

1. The blood fructose tolerance tests have been shown to be unaltered in diabetic subjects even in the absence of exogenous insulin.

2. Fructose produces a much greater rise in blood pyruvic acid as compared with glucose and this rise is the same or greater in diabetes.

3. In hepatic vein catheterization studies, the livers of both normal and diabetic subjects remove intravenously administered fructose twice as rapidly as they do glucose in comparable situations.

4. A considerable portion of administered fructose is converted in the body but the net advantage of fructose over glucose in diabetic subjects is between 20 and 25 per cent.

5. Oral administration is less advantageous, probably because of further conversion of fructose to glucose by the intestinal mucosa during absorption.

6. It has been shown that stress situations (for example, trauma, infection, ether-anesthesia, and starvation states) do not depress fructose metabolism as they do glucose.

7. Studies in diabetic acidosis indicate the value of fructose in the initial hours of therapy.

8. The use of intravenous fructose in place of glucose seems indicated also in diabetic patients who have just undergone surgery, who have febrile illnesses, or who otherwise may be expected to manifest the insulin resistance accompanying the alarm reaction. In such situations, the use of 5 per cent or 10 per cent solutions of fructose results in less hyperglycerine, hyperglycemia, and glycosuria. This provides for greater retention of carbohydrate and of total available calories than when glucose is used. Moreover, more efficient utilization of this carbohydrate serves as a prophylaxis against the development of ketosis.

9. There is an additional advantage which becomes apparent from these studies: The surgical patient who postoperatively would have greater utilization of available calories in the sugar given, if fructose were used; and the fluid balance would be more easily regulated because of the comparatively minimal diuretic effect when compared to glucose. The direct tissue utilization, especially in patients with minimal liver reserve, would also suggest an advantage in the use of fructose in the surgical patient.

So-called Mesenteric Adenitis

A Clinical Entity or Wastebasket Diagnosis?

EARL E. GAMBILL, M.D.
Rochester, Minnesota

From the Section of Medicine, Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

SO-CALLED mesenteric adenitis has been described in various ways by different authors. Generally it is reported to be characterized by the picture of acute, often recurrent, abdominal pain of variable severity and location, commonly in the periumbilical and right lower abdominal regions. It is reported that there may or may not be associated nausea and vomiting, diarrhea or constipation, mild fever and leukocytosis. Abdominal muscle spasm and tenderness in various areas are common. Enlarged intra-abdominal lymph nodes have been reported to be palpable. In some instances, regional or generalized lymphadenopathy is described. On occasion, malaise, headache and acute upper respiratory infections have preceded the abdominal pain. The condition has been described more commonly in children and young adults. The chief finding reported by surgeons has been enlarged mesenteric lymph nodes. Discussions as to the etiology, except from some patients with tuberculous adenitis, a condition seen more frequently in earlier years, have dealt heavily with theory and lightly on actual facts. The multiple theories as to the etiology of so-called mesenteric adenitis tend to emphasize the lack of specific knowledge, and the frequent failure of the pathologist to find an actual adenitis raises the question: Is there such an entity as mesenteric adenitis, or does the term merely signify a nonspecific condition of enlarged mesenteric lymph nodes associated with a variety of clinical states?

The current study was originally prompted by the experience of seeing a patient with idiopathic periodic peritonitis. A search of the files for records of other such cases disclosed a number of cases in which enlarged mesenteric lymph nodes were also associated with a variety of surgical conditions in the abdomen and which were labeled mesenteric adenitis. This prompted a study of all the cases in which this diagnosis had been made and an operation had been performed at the Mayo Clinic in the years 1948 through 1953.

Analysis of Cases

The series consisted of thirty-three patients. There were twenty males and thirteen females. The ages of the thirty-three patients ranged from one to fifty years; nineteen were more than fifteen years old, the ages of twelve being between twenty and thirty years with a median age of twenty for the males and of nineteen for the females.

The duration of symptoms ranged from one to fifteen years. Fourteen patients had had trouble for two or more years, and seven for five or more years. Five patients had undergone appendectomy at periods varying from three to thirteen years previously without relief of the attacks. The remaining fourteen had had only one attack prior to exploration.

Abdominal pain was the most prominent symptom, being present in thirty-two of the thirty-three cases. One patient underwent abdominal exploration solely because of profuse rectal bleeding. The primary site of pain was periumbilical or midabdominal in eleven cases, right abdominal in eight, infra-umbilical in four, epigastric in two, left abdominal in two, generalized in two and unspecified in four. The pain tended to shift to the right lower quadrant of the abdomen in thirteen cases. It was severe in thirteen, mild to moderate in seven, and absent in one; the intensity was not recorded in twelve cases.

The duration of the attacks of abdominal distress varied rather widely, from one hour to as long as four weeks. In particular, the duration was one to eleven hours in three cases, twelve to twenty-four hours in four, two to six days in eight, and more than six days in four; duration was not recorded in fourteen cases.

Laboratory and X-ray Data.—Laboratory studies did not reveal any diagnostic features and in general gave results that were nonspecific and

not helpful. The leukocyte count was 12,000 or more per cubic millimeter of blood in eleven patients. Neutrophilia was observed in six patients and eosinophilia in two (26 per cent and 15 per cent eosinophils respectively).

The sedimentation rate was less than 20 mm. in one hour (Westergren method) in fourteen of eighteen cases. Urinalysis gave no significant information.

In five patients, x-ray studies suggested abnormalities such as distended small-bowel loops, internal hernia, and intussusception. In two of these patients, operation did not confirm the suspected abnormalities.

Diagnosis.—A preoperative diagnosis of acute appendicitis was made in thirteen patients but was confirmed at exploration in only three. Meckel's diverticulum was considered among other possibilities in ten patients and found in two. Intestinal obstruction was suspected in four patients and confirmed at exploration in all four. In only one of the thirty-three patients did the clinician suspect mesenteric adenitis, and this was one of two possible diagnoses. Illustrative of the frequent lack of a clear-cut clinical picture is the fact that two or more possibilities were given as the preoperative diagnosis in thirteen cases. Among these possibilities were regional ileitis, volvulus, intussusception, adhesive bands, tumor of small bowel, irritable colon, recurring idiopathic peritonitis, mesenteric adenitis, internal hernia, mittelschmerz, and penetrating duodenal ulcer. The diagnosis was confirmed for patients having intussusception, mesenteric adenitis or penetrating duodenal ulcer and for those probably having recurring peritonitis.

Surgical Findings.—Appendectomy was performed in twenty-six patients but in only three was the appendix acutely or subacutely inflamed; in the remaining twenty-three, it showed only insignificant, chronic changes.

Enlarged mesenteric nodes constituted the only significant abnormality found at exploration in fourteen patients. In the other patients, the associated conditions found included Meckel's diverticulum (two patients), chronic cholecystitis and cholelithiasis plus duodenal ulcer (one patient), and one case each of the following: torsion of mesentery of small bowel, numerous adhesions in left upper quadrant along with perinodal inflammation, acute intestinal obstruction due to two sites of intussusception, "colitis" as described by the surgeon but with negative x-ray findings, hypertrophied Peyer's patches, intestinal obstruction due to remnant of omphalomesenteric duct, generalized inflammation with fibrinous exudate over small bowel, enlargement and thickening of small bowel, intestinal obstruction due to malrotation of cecum, and inflammation and edema of mesentery of small bowel. Five patients had a small amount of ascitic fluid, varying from serous to turbid in type.

Mesenteric lymph nodes were studied histologically in only ten patients. They showed nonspecific inflammatory changes. In two patients there were caseous granulomas of the lymph nodes, but extensive bacteriologic studies did not reveal any microorganisms including tubercle bacilli, fungi or Brucella. There was ulceration in the diverticulum of one of the two patients with Meckel's diverticulum.

Follow-up Data.—Follow-up data are scant and inconclusive. One of the three patients with acute or subacute appendicitis reported the recurrence of periumbilical pain with fever 16 months postoperatively. Follow-up information is available on only two of the 14 patients in whom nothing was found other than enlarged mesenteric lymph nodes. One of these continued to have attacks of abdominal pain 8 months after operation, while the other had had no further attacks when heard from seven months thereafter.

Among the patients who had other abdominal conditions associated with enlarged mesenteric nodes, one of the two with Meckel's diverticulum had had no recurrence of pain one year postoperatively. The patient who had numerous adhesions in the left upper part of the abdomen along with diffuse inflammation about the mesenteric nodes was continuing to have attacks of abdominal pain 14 months after operation. The patient with two intussusceptions had an episode of abdominal pain fourteen months postoperatively. The patient from whom a remnant of the omphalomesenteric duct had been removed because of intestinal obstruction was having intermittent cramps with passage of dark red blood by rectum one year postoperatively. The patient with malrotation of the cecum had an attack of abdominal pain six months after operation. The patient with diffuse inflammation and edema of the mesentery of the small bowel was apparently continuing to have attacks of pain four and one-half years postoperatively.

A patient who had considerable gray fluid in the peritoneal cavity along with enlarged mesenteric nodes and whose duodenum was not examined at exploration was subsequently found to have a duodenal ulcer. The abdominal pain of which he had complained disappeared following antiulcer therapy and did not recur during the subsequent follow-up period of five and one-half years. It does not appear that the preoperative pain was due to the duodenal ulcer, as it occurred in bouts lasting twelve to fourteen hours in association with fever and with tenderness localized in the right lower part of the abdomen.

Comment

It is evident that enlargement of mesenteric lymph nodes may occur alone or in association with a variety of pathologic states within the abdomen. The etiologic relationship between the enlarged nodes and the associated pathologic states that are described is not clear. The fact that in some patients the attacks of abdominal pain have continued after removal or correction of the pathologic conditions associated with the enlarged nodes suggests that, in some individuals at least, there may not be an etiologic relationship.

In fourteen of the thirty-three patients, enlarged mesenteric lymph nodes were the only finding noted by the surgeon. In these patients there was insignificant abnormality of the appendix. Thus, it seems that enlarged mesenteric lymph nodes may be the only finding in some patients with abdominal pain. In most of these, while the nodes may appear to the surgeon to be enlarged, an actual adenitis does not exist from the viewpoint of the pathologist. It would seem wise, therefore, that the surgeon and clinician in such instances avoid making a diagnosis of "mesenteric adenitis." A preferable diagnosis would be "indeterminate abdominal pain with enlarged mesenteric lymph nodes," care being taken to determine whether the nodes are in fact actually and significantly enlarged. Since enlarged mesenteric nodes may be associated with a large variety of intra-abdominal conditions, any one of which is capable in itself of producing abdominal pain and other clinical features ascribed to so-called mesenteric adenitis, the writer seriously questions the wisdom of making such a diagnosis even in those patients in whom at exploration enlarged mesenteric lymph nodes constitute the only finding. Such a finding is particularly common in children, and unless histologic study demonstrates definite acute or subacute inflammation or necrosis it would seem best to avoid the term "mesenteric adenitis."

This study clearly illustrates the fact that enlarged mesenteric nodes may be seen in association with a great variety of pathologic conditions within the abdomen, that a true adenitis was uncommon and that a single common specific etiologic factor was absent. The author believes it is wisest to assume that in almost all cases, enlarged and even inflamed nodes found by the surgeon should be considered the result of some other condition, even if undiscovered, which in itself is responsible for the clinical picture, rather than to assume that the symptoms are due to the adenopathy. To continue to make an unwarranted diagnosis of mesenteric adenitis is somewhat analogous to making a diagnosis of fever or leukocytosis without qualification. Surgeons and clinicians could do a real service by reserving the diagnosis of mesenteric adenitis for those patients in whom the nodes are definitely inflamed, to insist on critical pathologic and bacteriologic studies, and to consider the condition as probably a finding associated with or resulting from a more fundamental diseased state, specified if known, or designated as indeterminate if unknown.

Summary

A review of the records of thirty-three surgical patients in whom a diagnosis of mesenteric adenitis had been recorded disclosed that: (1) enlarged mesenteric lymph nodes constituted the only surgical finding in fourteen patients, (2) such nodes were associated with a wide variety of intra-abdominal pathologic states in nineteen patients, (3) a diagnosis of acute appendicitis had been made in thirteen but confirmed at exploration in only three patients, and (4) there were twenty males and thirteen females, the mean age being nineteen and one-half years.

Perhaps it might be well to discard the concept of mesenteric adenitis as a definite clinical entity. It is suggested that the designation be reserved for those cases in which there are frank inflammatory changes and that it be followed by such qualifying terms as "secondary to" or "associated with" (specifying the pathologic condition) or, when not associated with other demonstrable intra-abdominal pathologic conditions, by the term "of indeterminate etiology."

Present Status of Pituitary Hormone Preparations and Assays for Pituitary Hormones in the Blood

ROBERT H. KOOIKER, M.D.
Minneapolis, Minnesota

From the Department of Laboratory Medicine, College of Medical Sciences, University of Minnesota, Minneapolis, Minnesota.
Dr. Kooiker is a Medical Fellow Specialist, U. S. Public Health Service, grant No. 5222.

UNTIL relatively recently, the study of the various anterior pituitary hormones was limited to ablation techniques to determine their biologic actions. Replacement studies utilizing crude extracts of the pituitary gland offered more refined and accurate methods of determining their individual actions. However, interdependent or synergistic actions renders accurate knowledge of their individual biologic effects difficult of determination. Indeed, some authors have been skeptical of the view that the anterior pituitary secretes a different hormone for each effect, and in at least one case, thought that somatotrophin alone, or combined with adrenal-cortical-trophic hormone, could account for all of the effects attributed to the various anterior pituitary hormones.[1] Bioassay techniques were developed and improved. With this improvement came greater purification of the various hormone preparations, and increasing evidence that physiologic differences existed. Evidence was also gathered that species differences existed for the various hormones, as to activity and characterization.[2-4] Procedures for the preparation of the purified fractions are technically difficult and time-consuming, and therefore at present are not adaptable for the routine clinical laboratory. The bioassay methods presently available suffer from the same difficulties, and in addition do not allow for accurate quantitative determinations suitable for clinical use. More sensitive procedures are needed; these depend upon the development of purified preparations and of quantitative techniques which are sensitive enough to determine the amount of the desired hormone in biological fluids.

Bioassay methods exist for the presently known pituitary hormones, but the methods of assay for the pituitary gonadotropins are the only ones used with relative frequency. This is due to the fact that the remaining hormones are present in relatively minute quantities, and procedures such as precipitation with solvents and of subsequent dialysis to concentrate the desired constituent are necessary. The bioassay procedure most used for growth hormone is that of Evans and his colleagues,[5] which depends on growth changes in hypophysectomized rats. Hypophysectomy causes regressive changes of the proximal epiphysis of the tibia; changes which are reversed by the administration of growth hormone. Other tests sometimes employed are based on a gain in weight of female rats which have attained a weight plateau, and which, on administration of growth hormone, resume their growth.

Assay procedures for thyrotropin[6] are based on three general types of assay. The first determines morphologic alterations in the thyroid gland. The second measures increase in release or uptake of iodine, and the third measures increase in the discharge of thyroxin. These require concentration of the thyrotropin, which is generally accomplished by precipitation of the blood proteins with 50 per cent alcohol; the hormone remains in the supernatant fluid and is subsequently concentrated by dialysis. Various test animals are then used, including tadpoles, chicks, and guinea pigs.

Pituitary gonadotropins are measured by somewhat similar techniques.[7] The hormone in the urine is concentrated and injected into immature rats or mice. Changes in ovarian structure or in the weight of the uterus, are measured in relation to a similar group of controls receiving saline.

Statistically speaking, however, the accuracy of these bioassay methods depends on the attention to details which are beyond the control of all but the most rigidly operated laboratories. Granted the ability to rigidly control all conditions, these

assays would appear to be capable of a quantitative estimate of the presence of the hormone to be measured to within a two-fold level which would be within the useful clinical range.

Preparation of anterior pituitary hormones and their purification in relationship to homogeneity and characterization have been reported by numerous investigators. These include somatotropin,[8,9] thyrotropin,[10] pituitary gonadotropin,[11] and interstitial-cell-stimulating hormone.[12] The methods for preparation and purification are similar for all, and have been evolved from techniques developed for animal preparations.[13-15] These techniques basically consist of homogenization of the fresh pituitaries in various solvents and by pH precipitation of the various fractions. The resultant precipitate, redissolved in various solvent solutions, or the supernatant fluid, are applied to a chromatographic column packed with a resin, the composition of which will vary depending on the material being processed. The active constituent is eluted from the column with buffered salt solutions, and may then be checked for homogeneity by other chromatographic techniques or electrophoretic studies. Purity of the various hormones achieved by these generally applied methods is apparently excellent. However, immunologically, there may be considerable contamination with other hormones.[16] The biologic activity of these preparations must still be determined by the bioassay techniques previously mentioned. The purified material thus obtained, has in some instances, been subjected to a variety of conditions, both physical and chemical, with the demonstration that the different conditions of treatment can alter the chemical structure without apparent changes in biologic activity, or conversely, diminish the activity, or ablate it entirely.[17,18]

Structurally, all of these hormones appear to be polypeptide chains with variable amino-acid content and different terminal amino-acid groups. In the case of growth hormone, the amino-acid characterization includes a terminal group reported to be phenylalanine.[19] Some of the conditions referred to above rendered this hormone biologically inactive without apparent alteration in its chemical structure. Other conditions of treatment altered the chemical composition but did not affect biologic activity. Many of the methods for preparation of the different hormones which are obtainable from pituitary glands, and which are reported to be biologically active, have not been accompanied by characterization of the fraction, which renders comparisons and interpretation of the literature difficult.

Clinically, methods for precise determination of the presence and quantity of the various hormones would be advantageous. Due to the minute quantities present in biological fluids, extremely sensitive techniques approaching the usual level of accuracy of chemical determinations are needed. Concentration techniques for the different hormones have been employed, and are feasible in at least some instances, but do not allow for precise quantitation. Immunologic techniques, as a higher level of assay procedure, offer an attractive method of approach. These methods, however, depend upon the ability of the hormones to be antigenic for animals. It has been shown that at least one such preparation, human growth hormone, is antigenic, and is capable of producing antibody of sufficiently high titer as to allow the measurement of less than one microgram of the purified preparation, employing the precipitin ring technique.[20] Other immunologic techniques could also be used with the possibility of increasing the sensitivity, such as hemagglutination techniques, or use of a hemolytic system employing sensitized erythrocytes. Such a hemolytic system has been employed in the development of a procedure for the detection of antibodies to insulin, and apparently this method can determine extremely low levels of antigen-antibody reaction. This is the bis-diazotized benzedine sensitization of erythrocytes.[21] Immunologic techniques, however, require highly purified preparations, free from all other hormone activity. As reported by one investigator, an apparently homogenous preparation of growth hormone contained sufficient contamination with another hormone so as to seriously affect the specificity of the precipitin reaction.[22] The possibility remains, however, that there may be a difference between biologic activity and immunologic specificity, although the study just cited indicated that antibody was capable of neutralizing the activity of the growth hormone used as the antigen.

As a result of the above-mentioned findings, it was suggested that a clinical application might be made of these procedures. An attempt to develop a method for the measurement of growth hormone in blood was therefore undertaken, under the guidance of Dr. James Melby, of this department. Biologic activity of the material used as the antigen in this study has been determined by Doctor

Melby. Electrophoretic studies of this material indicate that it may not be a homogenous product, but consists of what appears to be three electrophoretically-separable bands. In the absence of additional available material of sufficient purity to determine additional antigenic components by absorptive techniques, it is felt at the moment, that this method may measure other components. A brief description of the method of adaptation is presented. It is to be stated that clinical application of this method has not been attempted as yet, because of the lack of knowledge as to the specificity of the reaction, and a desire to increase the level of sensitivity of the method.

Purified human growth hormone, prepared from frozen pituitaries provided by us, and processed through the courtesy of Dr. Norman Brink, Merck and Co., Inc., Rahway, New Jersey, serves as the antigen. This material is reported to be 80 per cent protein. One milligram of hormone, calculated from the protein content, is evenly suspended in Freund's adjuvant, complete type (Difco Laboratories), to a volume of 0.4 cc. Mature New Zealand White rabbits are then injected intracutaneously with 0.1 cc. in each of four sites: over each scapula, and over each side of the sacrum. Thirty days later, a saline solution of the antigen is given intravenously via marginal ear vein; 1.0 mg. being given on day 31, 3.0 mg. on day 33, and 6.0 mg. on day 35. Ten to twelve days later, the animals are bled by cardiac puncture of 20-25 cc. of blood which is pooled. The serum is removed and stored frozen in small aliquots until use. At approximately sixty-day intervals, the series of intravenous injections is repeated, and additional blood collected in the same fashion, for a continuing harvest of antiserum. Standard precipitin ring techniques are used to determine the smallest amount of the antigen which can be detected with a 1:2 dilution of the prepared antiserum. Quantitative tests, using bis-diazotized benzedine sensitized human "O" erythrocytes in a hemagglutination reaction are then carried out. By the use of these methods, quantities of human growth hormone, as a saline solution of the antigen material, of 1 microgram or less can be definitively determined. It would appear from the reports available as to the concentration of growth hormone present in the blood, that this present level of measurement would allow determination of growth hormone content in at least some clinical conditions.[23] Attempts to utilize the sensitized cell system in a complement fixation test, to produce hemolysis which can be quantitated spectrophotometrically have so far not been successful. The presence of non-specific hemolysins renders the proportional release of hemoglobin as a function of concentration of antigen, highly inaccurate. Developmental work is hampered by small supplies of the purified human growth hormone, which is necessary for continued preparation of antibody serum and for control quantitation studies.

Summary

The present status of anterior pituitary hormone preparations is presented. The problems of their preparation and purification are briefly discused. Present methods of bioassay are outlined. An attempt to adapt immunologic methods for their measurement is presented, which, it is hoped, will be capable of further development and subsequent clinical usefulness.

Rochester, Minnesota

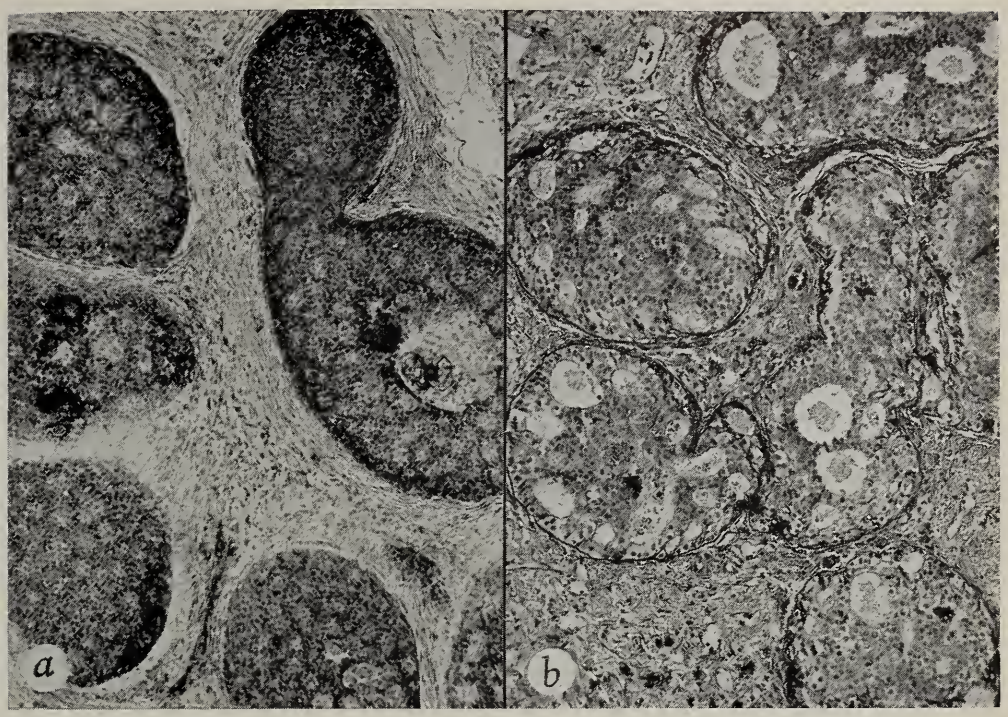

Fig. 3 (Case 3). *(a)* Comedocarcinoma of breast with focal calcification. *(b)* Metastatic tumor in lung, showing resemblance to comedo picture of primary lesion and focal calcification (both, hematoxylin and eosin; x100).

The sword of Damocles continues to hang over the head of the woman who has had a mammary carcinoma removed until she can be assured that metastasis is no longer possible. Cure often is assumed if five years have passed without recurrent lesions. In these three cases, metastasis first appeared as long as twenty-four years after the primary tumor was removed. Thus, the possibility of long-delayed metastasis should be considered in the prognosis of carcinoma of the breast.

THE concept that long-delayed metastasis may arise from neoplastic cells that have lain dormant was advocated by Willis[1], who stated that the secondary growths originated from tumor emboli present prior to surgical removal of the primary cancer. This variant in the behavior of malignant tumors is observed most commonly in carcinoma of the breast and melanoma, although latency has been noted in other cancers[2].

Chauffard[3] reported something of a record for delay in the appearance of local recurrent lesions; his patient sustained malignant recurrence in the surgical scar resulting from a mastectomy performed fifty years previously. Distant metastasis manifested as peritoneal carcinomatosis forty-one years after radical mastectomy was reported by Doyle and Hummer,[4] who demonstrated metastatic tumor cells in a peritoneal aspirate and also at necropsy.

Although delayed metastasis is reported fairly frequently,[2,5] it is probably rare in clinical practice. Hence, the following three cases are reported.

From the Sections of Medicine and Surgical Pathology, The Mayo Clinic and Mayo Foundation, Rochester, Minnesota. The Mayo Foundation is a part of the Graduate School of the University of Minnesota.

Doctor Degnan is a Fellow in Medicine, Mayo Foundation.

Report of Cases

Case 1.—A thirty-six-year-old white married woman first sought medical attention at the Mayo Clinic in November 1938, in order to determine whether a relationship existed between a nodule in the right breast and pain in the right arm. The nodule had followed trauma five years previously, whereas the pain had been present for one year. One month prior to admission, she had undergone biopsy of the nodule elsewhere, and mastectomy had been advised. Positive physical findings included a healing incision of the right breast, a retroverted uterus with a small fibroid, and slight enlargement of the left lobe of the thyroid. Axillary nodes were not palpable.

Microscopic examination of the tissue brought by the patient revealed a typical low-grade comedocarcinoma of the breast (Fig. 1a). It was multicentric, and numerous ducts were distended with uniformly large hexagonal cells. A cribriform pattern was present, giving the nests of cells an aspect reminiscent of that seen in adenocarcinomas of the cylindroma type. Some periductal fibrosis was apparent, which was taken to represent a defense reaction that tended to localize the growth within the ducts. This barrier was breached in some zones, with malignant cells streaming out into the periductal fibrous tissue.

Right radical mastectomy was performed. Lymph-node metastasis was not found. Three courses of roentgen therapy followed.

The patient was examined on numerous occasions through 1956, and evidence of recurrence was absent at all times. In January 1960, she returned because of a two-year history of chronic productive cough. Hoarseness that followed a "cold" had been present for three months, accompanied by a loss of 6 pounds. Examination revealed diminished breath sounds over the posterior aspect of the right lower lung and a mass in the right supraclavicular area. Thoracic roentgenograms revealed an elevated right diaphragm, the movement of which on fluoroscopic examination appeared to be paradoxic and almost completely absent. Paralysis of the left vocal cord was noted at laryngoscopy.

Biopsy of the right supraclavicular mass revealed a nodal metastatic tumor that likewise featured a well-differentiated adenocarcinoma in which the cells were large and uniform and were growing in large clumps or aggregates (Fig. 1b). The patient subsequently received radiation therapy.

Comment.—Metastasis to the supraclavicular and mediastinal regions appeared in this patient twenty-two years after mastectomy and radiation therapy.

Case 2.—In April 1941, a fifty-one-year-old white married woman came to the clinic because of puckering of her left breast of several months' duration. In addition, she had noted soreness of the nipple for seven weeks, pain for four weeks and enlargement of the breast for seven days. Examination revealed a firm lump in the area of puckering in the left breast.

Left radical mastectomy was done. Pathologically, the mammary lesion in this case exhibited comedo features like those in Case 1, but much of the growth was typical of grade 3 scirrhous adenocarcinoma (Fig. 2a). The aggressiveness of the lesion was further apparent by the presence of metastatically involved axillary nodes. The patient subsequently received three courses of irradiation.

In July 1942, the patient received a course of irradiation for spinal pain, although abnormal findings were not elicited. She was seen at frequent intervals subsequently, with no evidence of recurrence. In October 1942, radium therapy was given for a benign, cellular, mixed tumor of the left parotid gland.

The patient was asymptomatic until March 1956, when she complained of a cough of six weeks' duration. Abnormal physical findings were not present, but roentgenograms of the thorax revealed a nodule along the right border of the heart.

Thoracotomy disclosed a nodular mass in the tip of the middle lobe of the right lung, adherent to the pericardium. Multiple small nodules characteristic of metastasis were distributed widely over the pleura. Two nodules were biopsied, and the findings were so typical of metastatic mammary carcinoma (Fig. 2b) that no thought was entertained concerning other possibilities. It was considered that nothing could be gained from resection and no therapy was given.

From October 1956 until September 1959, she was seen on five occasions for persistent cough, recurrent chills, fever, aches, and loss of weight. In September 1959, dullness with diminished breath sounds was noted at the base of the right lung. At bronchoscopy, a lesion thought to be malignant was found; however, microscopic examination revealed inflammatory changes. Radiocobalt (Co^{60}) therapy was administered.

When the patient was last examined in February 1960, fever was again present. It was attributed possibly to a current urinary infection, long-standing diverticulitis or the malignant lesion. Roentgenologic studies revealed a pleural reaction with possible effusion on the right. Antibiotics were given.

Comment.—Metastatic carcinoma of the lung developed in this patient 15 years after mastectomy for mammary carcinoma. The patient continues to live despite widespread pulmonary metastasis.

Case 3.—A fifty-one-year-old white unmarried woman was examined in February 1935, because of a tumor of the right breast of one week's duration associated with some pain, redness and soreness. Similar findings, noted one year previously, had resolved except for the presence of some local tenderness. Examination revealed a mass in the outer quadrant of the right breast, and an enlarged lymph node was felt high in the axilla.

Radical mastectomy was performed. The microscopic picture of the mammary lesion duplicated in all essential aspects that previously described in Case 1. The comedo-

carcinoma was of grade 2 malignancy, with zones of calcification (Fig. 3a). It was easy to find zones of periductal extension, and the scirrhous reaction was apparent in such localities. Axillary nodes were involved metastatically.

In July 1935, metastatic lesions were noted in the right humerus, and radiation therapy was administered; two additional courses were given in August 1935, when further progression was noted. On subsequent visits, the roentgenographic appearance of the lesions showed improvement. In 1941, another course of radiation therapy was administered for dorsal vertebral pain, although abnormalities were not found.

Periodic visits did not reveal any evidence of recurrence until August 1959. At this time, the patient complained of anginal pain and a "low blood count." The presence of pulmonary metastasis was suggested by thoracic roentgenography, and left lower lobectomy was performed. The pulmonary metastatic lesion was a well-differentiated adenocarcinoma with honeycombed plugs of malignant cells that here and there exhibited foci of calcification (Fig. 3b). Resemblance to the comedo picture of the original lesion was striking.

At her last examination in December 1959, further recurrence was not evident.

Comment.—This patient had radical mastectomy for carcinoma in 1935. Shortly thereafter, osseous metastatic lesions were discovered and treated with irradiation. Further recurrence was not observed for twenty-four years, at which time pulmonary metastasis became evident.

General Comment

As stated initially, long-delayed metastasis implies growth of latent malignant cells. The cause of this intriguing behavior of cancer, illustrated by these three cases, is probably unknown. In Cases 1 and 3, the primary lesions were well-differentiated comedocarcinomas with low potentials of growth. The tumor in Case 2 likewise exhibited comedo features. However, lack of aggressiveness cannot explain the bizarre behavior of the lesions. Thus, although the delayed recurrence in one instance was the first evidence of metastasis, long periods of restraint of growth ensued in the remaining two patients, although early metastatic lesions were found.

The arrest of growth is attributed by many investigators[6-8] to local tissue resistance. Some change in the quality or restraining influence of the tissue apparently allows regrowth of cells. Hadfield[9] thought that curtailment of growth in local lymph nodes is secondary to anoxia or to entrapment of the malignant cells in fibrous tissue. Revascularization produced by inflammation allows further regrowth. However, it is a well-documented fact that the scirrhous reaction which appears to "strangle" the cellular elements in certain instances of linitis plastica is associated with a five-year survival rate of about 5 per cent.

Gatch[10] stated that the cohesion of malignant cells provides for containment of growth, whereas loss of cohesion is followed by dissemination. In this connection, the coherent pattern of growth observed in Cases 1 and 3 is interesting.

Hadfield[9] cited experimental evidence to explain the concept of dormancy. He drew a parallel between the long survival of rapidly frozen malignant cells and the naturally occurring dormant state. The faculty for survival is attributed to intracellular dehydration, with concentration of nucleic acids. This occurs in undifferentiated paramorphic cells.

A recent report[11] by a committee of the American Medical Association noted the dramatic effect of the menopause on duration of the latent period in recurrent mammary carcinoma. In a group of forty-eight patients in whom the menopause was interposed between the primary disease and the detection of the recurrent lesions, the duration of occult metastasis averaged eighty-seven months. When both events occurred either before or after the menopause, as in 501 cases, the interval was less than half this value. In a companion editorial, Macdonald[12] stated that the group in which the menopause occurs during the latent period should be separated from any large series because it affects the survival figures disproportionately.

In our Case 1 the menopause intervened between the primary tumor and the recurrent lesions, whereas the primary growth occurred during the menopause in Case 2; the menopause antedated both events in Case 3. Thus, the menopause intervened in only one of our cases. Nevertheless, the behavior of the latent cells apparently is considerably influenced by the hormonal environment.

Some insight into this problem may be gained by examining some recent advances in the field of cancer immunology.[13-16] A recent review by Black and Speer[13] is pertinent and forms the basis of much that follows. Current thought suggests that canceration of cells is frequently, if not always, associated with variable degrees of new antigenic changes. The latter may be the result of the creation of new antigens or the partial depletion of "normal identity" antigens or both.[13]

In carcinoma of the breast, the presence of lymphoid infiltration in the primary tumor,[17] sinus histiocytosis,[18] and metallophilia[19] in the local lymph nodes has been interpreted by some observers as evidence of local antigenic response to malignant growth. Systemic manifestations suggesting antigenic response are the demonstration of circulating antibodies,[20] increase of serum globulin (especially the alpha fraction), depression of properdin levels,[21] and the presence of hemolytic anemia.

Colonic carcinoma gives little evidence for antigenic response, such as lymphocytic infiltration or sinus histiocytosis.[13] Perhaps the theory of a deficiency of "identity proteins"[22] (antigens) is more attractive here. This deficit of proteins could follow viral invasion, radiation and hyperplasia. With this deficiency of "identity marker" but not to a degree that prevents recognition, the cell does not elicit the usual regulating immunologic mechanisms. Miller and Miller[23] postulated gradations of depletion, with the most severe degree causing death of the malignant cell, a less severe alteration permitting survival with limited growth, and the least change permitting a potential for unlimited growth.

According to these theories, clinical aggressiveness would predominate when growth potential was high but the antigenicity of tumor cells or the responsiveness of the host or both were minimal; prolonged survival would be expected with low growth potential or a high degree of antigenicity and host responsiveness or both.[13] Latency could be visualized in the light of this immunologic host-tumor concept. Apparently the antigenic response to the host is such that for long periods, curtailment of growth occurs; with alteration in this status, the period of latency is terminated and uncontrolled proliferation of malignant cells ensues. Actually, long-delayed metastasis may well support the validity of this immunologic concept. Indeed, as Black and associates[24] advocated, the classic concept, which interprets cancer as a malignant primary lesion with linear temporal dissemination, needs reappraisal.

Summary

Three cases are reported in which long-delayed metastatic lesions from carcinoma of the breast occurred after intervals of twenty-two, fifteen, and twenty-four years, respectively. This intriguing behavior is best explained as a variation in the host-tumor relationship, in which the potential for growth is the reciprocal of tumor antigenicity or host responsiveness, or both.

Case Report

Three Malignancies in One Patient

G. CHARLES WILCOX, M.D.
Albert Lea, Minnesota

Read at the annual meeting of the Southern Minnesota Medical Association, Minnesota, September 14, 1959.

THIS IS a case of a twenty-five-year-old white woman who was first seen in November, 1955. She came to the office for the care of her first pregnancy. Her past history revealed that she had enjoyed good health, with the exception of having had an appendectomy in 1949 and later a pelvic inflammatory disease which cleared uneventfully under treatment. Physical examination revealed the patient to be approximately two and one-half months pregnant. She went to term, delivering a normal 6-pound, 2-ounce girl on May 15, 1956.

In November, 1957, the patient had what was thought to be a spontaneous complete abortion at two months in her home.

In August, 1958, the patient again came to the office for the care of a pregnancy. Physical examination indicated she was a little over two months pregnant, the estimated date of confine-

---

The illustrations are of tissue taken from the original surgery done in April, 1959.

1. Gross specimen of ovarian tumor comprised of dysgerminoma and teratocarcinoma.

2. Microscopic section showing junction of the two tumors of the ovary.

3. Microscopic section of the cervix showing the carcinoma *in situ*.

ment being February 22, 1959. Her pregnancy was uneventful except for an upper respiratory infection and a non-specific vaginitis in January, 1959. Under treatment, both of these conditions were relieved. On February 25, 1959, the patient delivered a normal 7-pound boy uneventfully. After a five-day hospital stay she was discharged.

On April 10, 1959, the patient returned to the office for her six weeks' post-partum examination. At this time a leukoplakia was discovered on the anterior lip of the cervix from which a Papanicolau smear was taken. The smear was reported to contain many malignant cells. Therefore, the patient was hospitalized and on April 17, 1959, a cervical amputation was done by Dr. D. K. Holian, of Albert Lea, and myself. At the end of this procedure, a pelvic examination revealed a right adnexal mass, previously not discovered. Consequently, three days later, a pelvic laparotomy was done which revealed the presence of an ovarian mass on the right side, approximately 6 to 7 centimeters in diameter, lying high in the posterior cul-de-sac. A frozen section of the mass indicated this to be a malignancy. Therefore, a panhysterectomy was done, along with removal of the peritoneum against which the mass was lying. No nodes or evidence of metastases were found. The patient recovered promptly from the surgery and was discharged from the hospital on Premarin 2.5 mg. four times a day. Soon after her discharge she developed a cystitis which cleared well on Furadantin 100 mg. three times a day.

On June 5, 1959, an Ascheim-Zondek test was run on a twenty-four-hour urine specimen and reported normal at 2500 to 3000 rat units. The normal for a three-month pregnant woman is approximately 50,000 rat units. This test was repeated during the first part of September with a result of 15 to 20 rat units.

The final pathology report from Dr. E. C. Menefee of Naeve Hospital, Albert Lea, was: (1) carcinoma *in situ* of the cervix; leukoplakia of the cervix and chronic cervicitis, (2) uterus with no residual carcinoma, (3) endometriosis of the right ovary and dysgerminoma of the right ovary associated with a teratocarcinoma of the right ovary, (4) no tumor invasion of the peritoneum specimens.

Summary

A twenty-five-year-old white woman, Gravida III, Para II, AB I was found to have a leukoplakia at her six-weeks' postpartum examination, confirmed by a Papanicolau smear. After amputation of the cervix, a right adnexal mass was discovered, and three days later a pelvic laparotomy was performed. Because of the presence of a large malignant tumor of the right ovary, a panhysterectomy was done. The pathologist's report included the following: (1) carcinoma *in situ* of the cervix, (2) dysgerminoma of the right ovary, (3) teratocarcinoma of the right ovary.

This case was of special interest to us because of the presence of three distinct malignancies in such a young patient. This case also supports the contention that regardless of age or physiological conditions, such as pregnancy, a Papanicolau smear can be justified to instigate procedures that may well save or prolong the life of the patient.

Sequel

Since the original report of this case, the following history may be recorded. Because of persistent bloating, obstipation, vomiting, and lower abdominal pain, the patient was readmitted to the hospital on October 5, 1959. The next day, a pelvic laparotomy was done and several omental and pelvic metastases were discovered. The liver was not involved grossly. A tumor, measuring 4 x 6 cm. was removed and the wound closed. The pathology report was: metastatic, anaplastic carcinoma (primary teratocarcinoma of the ovary). The patient was discharged on October 11, 1959.

Symptoms of partial small bowel obstruction soon reappeared and on November 13, 1959, the patient was again admitted to the hospital. Supportive treatment was offered and the patient expired on November 30, 1959. Permission for an autopsy was not granted.

The Story of Diphtheria

ROBERT ROSENTHAL, M.D.
Saint Paul, Minnesota

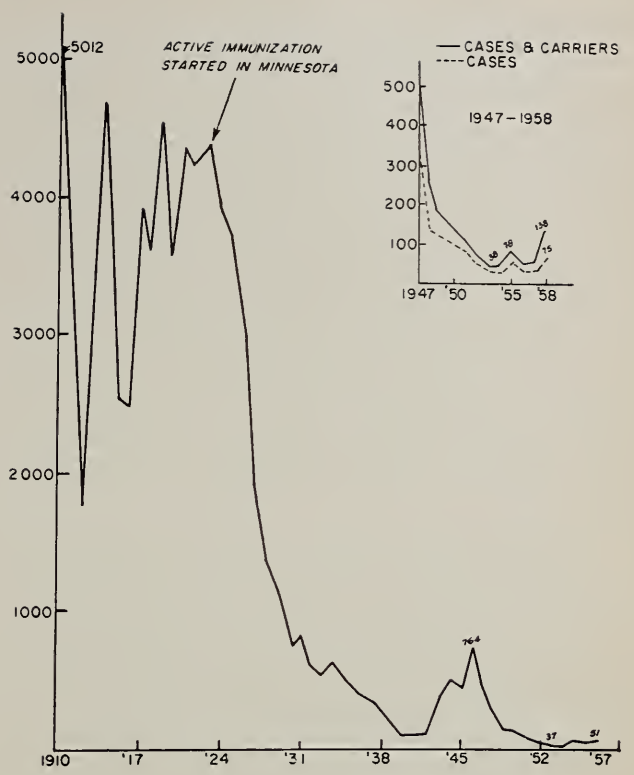

Fig. 1. Cases of diphtheria (plus carriers) in Minnesota, 1910-1958.

Presented at the meeting of the Minnesota Academy of Medicine, February 10, 1960.

DIPHTHERIA, a disease so ancient that its origins are uncertain, possesses a strange and fascinating history. It was truly a killer, and it struck children with dreadful severity. In the Minnesota north country, diphtheria was the persistent enemy of the pioneer, and, as late as 1910, there were in this state 566 deaths attributed to it. During the fifteen years following 1910, the mortality rate varied from 354 to 170 per year. In 1927, for the first time, the number of persons slain by the diphtheria was less than a hundred. The eventual conquest of such a killer should delight every physician, and it is the narrative of this triumph that I wish to sketch for you in the brief period allotted to me.

Fortunately, the history of diphtheria conveniently divides itself into six phases: (1) the development of the clinical picture, (2) the recognition of the disease's contagiousness and epidemicity, (3) the croup problem, (4) the discovery of the diphtheria bacillus, (5) the development of passive immunization with antitoxin, (6) the development of active immunization with toxin-antitoxin and, later, with toxoid.

Development of Clinical Picture

The development of the clinical picture, which brings us to the mysterious problem of the age of the disease, is, indeed, fascinating. Actually, no one can tell with exactness when diphtheria first appeared, because palaeopathology has not been able to prove its existence in prehistoric times.

However, Hippocrates apparently described a disease which can be identified with a fair degree of certainty as diphtheria. He used the name *cynanche,* a term which remained in medical literature until the nineteenth century. The word was derived from the terms *kyon,* meaning dog, and *anchein,* meaning to strangle. Later, it was applied to all types of obstructive conditions as the result of which a patient seemed to pant like a dog. Hippocrates mentioned the difficulties in deglutition, the escape of fluid through the nose when liquids were taken, the nasal voice, and the inability to stand upright. He also included in the term various forms of throat and laryngeal afflictions.

The next step was made in Galen's time, when a distinction was made between *synanche,* throat diseases, and *cynanche,* laryngeal affections. It was during this period that the term *angina* made its appearance and was used in the same sense. There is only one other chronological point to mention. If Susruta's medical writing is as old as is claimed, it may be that his description of the disease *Valasa,* as found in Sanskrit medicine, is, indeed, diphtheria and, therefore, ante-dates Hippocrates. Susruta wrote of a disease having the characteristics of painful swelling of the throat, difficulties in breathing, and, finally, asphyxia.

Conjecture flees before fact, however, in the writings of Aretaeus Cappadox, who usually is given credit for the first good description of diphtheria. This astute individual, straddling the first and second centuries A.D., wrote his excellent *Causes and Symptoms of Acute Diseases.* In it he described "ulcerations about the tonsils," which, he claimed, were called Syrian or Egyptian ulcers because of their prevalence in those countries. Many of the symptoms he described sound like those of diphtheria—the sore throat, the aphthae or ulcers in the throat, the inflammation of the neck glands, the involvement of the uvula, the hoarseness, and frequently sudden death. Aretaeus stated also that children up to the age of puberty were particularly prone to the disease.

During the sixth century, Aetius of Amida also described a similar condition and added the important statement that, when the throat healed, there might be some difficulty with the voice and that the patient might regurgitate fluids through the nose. He thus recognized post-diphtheritic paralysis.

During the next thousand years after the sixth century, only two or three accounts which conceivably might have been diphtheria appeared in the literature. It is true, of course, that, during the twelfth and thirteenth centuries, Gilbertus Anglicanus wrote of a Quincy-like sore throat which he called *squinantia* and which occasionally caused death by suffocation. And John Arderne, in the fourteenth century, gave the name *squynancy* to describe similar cases which he observed in England.

Recognition of Contagiousness and Epidemicity

By the sixteenth century, the disease had taken on epidemic proportions in the Low Countries, in the Rhine provinces, and in France. At this time we get the first unequivocal account of the disease. It was written by Guillaume de Baillou, who, by the way, has to his credit the first clear description of whooping cough. In the winter of 1576-1577, a surgeon told Baillou of an infant who had evidently died of laryngeal diphtheria. Autopsy showed a membrane in the larynx. Baillou could relate other like cases. His book, however, did not appear until 1640, twenty-four years after his death.

During the later part of the sixteenth century and throughout much of the seventeenth century, there were disastrous epidemics in Portugal, Spain, and in France. As a result, a voluminous literature developed in which many of the well-known names for diphtheria were coined. The Spanish used the name *garotillo,* because death from diphtheria reminded them of the effects of garotting, their national method of executing criminals. *Morbus suffocans* and *morbus strangulatorius* convey the same idea. Other writers, saying that the main symptoms are found in the throat, use the terms *anginosa passio* or *ulcera anginosa.*

Villa Real, an early Spanish writer, first mentioned the painlessness of the condition and the high mortality of the hemorrhagic form in his *De signis, causis, essentia, prognostico et curatione morbi suffocantis,* which was published in 1611. In 1620, Johannes Andreas Sgambatus gave the first modern account of diphtheria when he described an epidemic in Naples in his *De pestilente faucium affectu Neapoli.* Real wrote that the membrane formation does not necessarily lead to ulcerations. Cutaneous diphtheria first was mentioned by Perez de Herrera in 1615. He used the name *morbus*

suffocans garrotillo to describe the disease. Another Italian of the period, Aetius Cletus, wrote of the *morbus strangulatarius,* pointing out once again the characteristic paralysis. But he is clearer on this point than those before him, for he discussed both the difficulties in speech articulation and the nasal voice. It is significant to note that most of the authors of this period recognized the contagiousness and the epidemicity of diphtheria.

It may be worthwhile to note that perhaps the earliest illustration of a bronchial cast—probably diphtheritic—was published in 1641 in the *Observationes medicae* by Nicholas Tulp, who is so well known from Rembrandt's "Anatomy."

Five years later, in 1646, Thomas Bartholin published in Paris a volume describing the Italian epidemics. In this he gave a clear clinical appraisal of diphtheria, including its contagiousness and its toxic effects on the nervous system. He specifically mentioned paralytic strabismus in a child. He discussed also the advisability of tracheotomy. Indeed, it was at his request that Moreau of Paris wrote a short treatise on tracheotomy. This was printed with Bartholin's booklet. Moreau was competent, for he had successfully carried out this operation on two adults. He felt it should be used also on children to prevent death from asphyxiation.

As is generally true, the interest of the medical profession and the amount of literature decreased or increased in relation to the easing off of epidemics or their mounting severity. The late seventeenth century witnessed a marked increase of diphtheria epidemics, both in Europe and in America. Thus it was that a rash of literature began appearing on this side of the Atlantic, for diphtheria increased in the New World during the late seventeenth century and even more during the following century. When Cotton Mather wrote of the occurrence in 1659 of the "Malady of Bladders in the Windpipe" he thought he was dealing with a disease unknown in America. Yet, between 1735 and the 1750s, most of the New England states were to be ravaged by the disease. And there is no doubt but that the term "throat distemper" included diphtheria as well as scarlet fever. Writers wrote of swollen tonsils with membranes, marked general weakness, and skin eruptions. Samuel Bard of New York showed, by means of autopsies, the membrane formation in the trachea in every case of diphtheria. In 1771, he published his famous treatise, *An inquiry into the nature, cause and cure of the angina suffocative, or sore throat distemper, as it is commonly called by the inhabitants of this city and colony.*

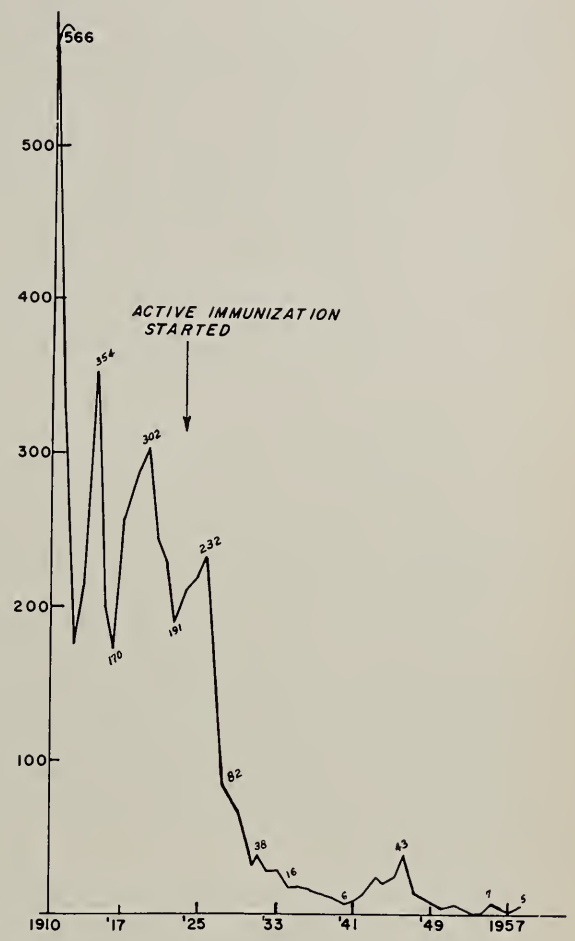

Fig. 2. Deaths from diphtheria in Minnesota, 1910-1958.

In Europe, diphtheria epidemics continued in decade after decade, so that numerous outstanding physicians became interested in the disease. Among these was John Fothergill, distinguished English clinician, who published his *Account of the sore throat attended with ulcers* in 1748. Most of the cases he reported, however, suffered from scarlet fever. Although it was occasionally suspected that two different diseases were confused one with the other, the distinction was not sufficiently clear to be accepted generally by the medical profession.

The Croup Problem

This confusion was compounded when Francis Home published in 1765 his famous *An inquiry into the nature, cause and cure of the croup,* a book

that became most popular. Home introduced the word *croup* into medical literature, taking it from the old Scotch word which meant the croaking noise of frogs or birds, and of children with laryngeal obstructions. It was used as a verb as early as the sixteenth century, but the noun did not appear until the eighteenth century. The confusion was manifested further in other designations of laryngeal afflictions—false croup, spasmodic croup, membranous croup, diphtheritic croup. In France, *croup* became synonymous with diphtheria. Many pamphlets and dissertations thus spoke of *angina membranacea vulgo croup vocata.* The Germans also adopted this word—especially the adjective—using either the German *crupöse* or the Latin *cruposus* to indicate an inflammatory condition accompanied by a thick exudate—croupous pneumonia, croupous laryngitis, etc.

The French were so conscious of the prevailing confusion that they offered prizes for the best clarifying essays. Such awards were sponsored by the Royal Society of Medicine of Paris in 1783 and by Napoleon in 1807. Napoleon was especially interested, for he was affected by the death from croup of Louis Bonaparte's son. The questions put to the essayists were: did croup actually exist in France? what were the signs to warrant the diagnosis of croup? what treatment was to be used?

It remained, however, for Bretonneau, Trousseau, and their fellow workers to place the whole question of diphtheria on a sound basis. Pierre-Fidèle Bretonneau, chief physician of the general hospital at Tours, was a fine clinician. With Dypuytren and Laennec, he had been a pupil of the great Corvisart. Among Bretonneau's achievements was his recognition of the intestinal lesions in typhoid fever. He had been able to observe, between 1818 and 1820, epidemics among soldiers and civilians. In soldiers, the disease, which was a condition of the mouth, was considered as a "scorbutic gangrene." Among civilians, it was thought of as a malignant angina. Bretonneau, after careful observations and sixty-one autopsies, wrote in 1826 his famous work on inflammations of the mucous membranes, which gave emphasis to diphtheria or membranous inflammation. With the publication of this distinguished volume, *diphtheria* (or *diphtherite* as Bretonneau termed the disease) was established as a specific disease. The word was coined from the Greek *diphthera,* which means a piece of leather. In 1855, Bretonneau altered the term to *diphtherie,* the equivalent of our diphtheria.

Bretonneau was convinced not only of the specificity of diphtheria but also of its contagiousness. He also suspected a single causative agent. This recognition of the identity of croup and malignant sore throat and of Bard's *angina suffacativa* had not been made clear since the work of Aretaeus during the first and second centuries. But this is not all. Bretonneau is important in the history of diphtheria for another reason: supposedly he carried out the first successful tracheotomy on a child suffering from the disease. This was done at Tours in 1825. One of his pupils, Armand Trusseau, later one of the greatest of French clinicians, popularized Bretonneau's ideas, favored tracheotomy, and performed the first one in Paris. It is said that he cured nine out of thirty-six patients by this operation.

Discovery of the Diphtheria Bacillus

After the middle of the nineteenth century, between 1856 and 1858, diphtheria epidemics became so widespread that medical authors began to speak of a pandemic. Thus investigations were increased and applications of all new medical knowledge were used. It is at this point that the period of experimental investigation begins. The result was that there was successful transmission to animals. This work was done by Friedrich Trendelenburg and Max Joseph Oertel in 1870. The next landmark was long in coming. Not until 1883 did Edwin Klebs find the causative agent of the disease. In Kleb's first report, he stated that he found bacteria only in the membrane and in no other portions of the body. A year later these findings were confirmed by Friedrich Loeffler, Koch's assistant, in the latter's Berlin institute. Loeffler made use of Koch's development, in 1881, of plates for cultures, confirmed most of Kleb's findings, and proved the susceptibility of animals. But even more significant was the fact that he found virulent diphtheria bacilli in a healthy child.

Although by the 1880's the knowledge of diphtheria had increased considerably, there were still problems. As yet no specific treatment had been devised. It was, of course, only natural, that physicians were particularly concerned both with the obstructive symptoms and with the techniques to

avert death from asphyxia. Successes with tracheotomy had not been too satisfactory. It was too formidable an undertaking for many physicians and procrastination, no doubt, was one of the reasons for so many failures. A substitute was needed that would be less drastic and would take the form of intubation of the larynx. This was found by Bouchut in Paris in 1858 and was termed *tubage*. Bouchut's early trials were not altogether successful, and of, course, there was opposition by Trousseau, who championed tracheotomy. A Scotsman, William Macewen, it will be remembered, used some kind of a catheter in 1881 with moderate success, but it must also be recalled that the catheter technique had been used by Desault before 1800. This apparently was not true intubation.

The technique was perfected after four years of work by Joseph O'Dwyer, who, in 1885, published the results of his experiments in the *New York Medical Journal*. A careful worker, O'Dwyer produced a tube that fitted exactly the inside of the larynx. His tube had a bulge so as to make expulsion by cough difficult. It was fashioned also so as not to slip into the trachea. The O'Dwyer tube, however, was not to become general until the serum treatment had been developed during the next decade. It is pleasant to say that the O'Dwyer method met with less opposition than is usually directed against radical innovations. It may be of interest to you that the intubation set now displayed in the museum of the Ramsey County Medical Society came from Dr. O'Dwyer himself. He presented it to Dr. James T. Christison, one of the pioneer pediatricians of St. Paul. Despite the rather general acceptance of the O'Dwyer method of intubation, there was a certain difference of opinion among members of the medical profession as to the relative merits of intubation and tracheotomy. During the past twenty or thirty years, intubation has practically disappeared.

Development of Passive Immunization with Antitoxin

Despite all this progress, a number of problems still awaited solution. These included the production of various symptoms of the disease, its treatment, and its prevention. That bacteria could not be found in internal organs was, of course, known as the result of the work of Klebs and Loeffler. It was therefore suspected that the bacilli produced a toxin. Emile Roux and Alexandre Yersin proved this to be so. They separated the toxin from the bacteria. When animals were inoculated with the toxin they showed diphtheria symptoms, resulting in death. The first animal work was done by Karl Fraenkel, who, in December 1890, immunized guinea pigs with attenuated diphtheria bacilli. On the day following publication of Fraenkel's guinea pig experiments, two other researchers, Emil von Behring and Shibasaburo Kitasato, published similar papers telling of their successes with immunization against tetanus. These two pointed out that the cell-free blood serum had the capacity of counteracting the toxin in animals. About the same time, Behring found the same to be true for diphtheria. These findings, then, were the foundation for the next, dramatic step. On Christmas night a year later, diphtheria antitoxin first was used on a child. Yet the technique did not become popular immediately. Several years were to elapse before the treatment became popular and to make serum available to those who wished it. Not until 1894-1895 did the treatment come to be accepted generally.

The first municipally operated health laboratory was established in New York City in 1892. There, a year later, bacteriological work on diphtheria was begun by William Hallock Park and his assistant, Alfred L. Beebe. These men showed the importance of carriers, and emphasized the necessity of taking cultures from well contacts in households where diphtheria was present.

Development of Active Immunization with Toxin-Antitoxin and with Toxoid

But, although now diphtheria could be diagnosed, carriers identified, and treatment begun, there remained two areas still to be developed. Prevention and control, in addition to isolation and quarantine, now hung upon the introduction of mass immunization. Animal immunization had been demonstrated in 1890. The next step was taken by Dziergowski. In 1902, he used diluted toxin in humans and thus was successful with active immunization. Theobald Smith suggested a neutralized toxin-antitoxin mixture, in 1909. In 1913, Behring, who had been experimenting with diluted antitoxin alone, successfully used a toxin-antitoxin mixture. In the same year, Bela Schick supplied a guide with minute amounts of toxin to be used for the several age groups and for purposes

of mass immunization. His test was also the means of getting the answer to the results of such immunization.

It was known, of course, that diphtheria toxin could be altered and mitigated by the application of either cold or heat, but it was most difficult to standardize, in dependable fashion, such treatment of the toxin. When, therefore, G. Ramon developed his formalin treatment and produced anatoxin, the toxin-antitoxin mixture was discarded quickly. This was especially true when reports of anaphylactic shock began to mount. The formalin treatment later was replaced by alum-precipitation, and this product, now known as alum precipitated toxoid, has been in use for over a quarter of a century.

The first mass immunization in the United States was begun in New York City, where by 1928, half a million children had been immunized. It was estimated that by 1940 about sixty per cent of all New York City children had received the preventive treatment. Mortality had decreased from 705 per 100,000 in 1894 to only 1.1 in 1940. It must be noted, however, that there was a spontaneous improvement in the morbidity and mortality of diphtheria. In New York in 1910, the mortality from diphtheria in children under ten years of age was only 300 per 100,000. This decline started before antitoxin was used extensively. By 1920, the mortality fell below 100. And this took place before active immunization really was in progress.

Minnesota figures tell the same story. In 1910, there were 5,012 reported cases of diphtheria. From that year until 1923, when active immunization began, the number of cases varied between 2,500 and 4,500 annually. Five hundred and sixty-six persons died from the disease in 1910. However, during the following fifteen years, the number of deaths varied from 170 to 350 per year. It is interesting to point out also that, although immunization began in 1923, there were 232 deaths in 1925. Then a rapid decline set in. By 1930, only 768 cases (plus carriers) and thirty-two deaths were reported. In 1950, in Minnesota there were ninety-nine clinical cases, thirty-seven carriers, and only eight deaths. The lowest point was reached in 1954 with fifty-four cases, thirty-seven carriers, and two deaths. In 1958, there were 138 cases and five deaths.

These figures, the result of long years of toil and patient research by men in many lands, show clearly that only continual and persistent watchfulness can keep diphtheria in shackles and under control. Epidemics do not die out completely. Yet this short narrative of diphtheria and its conquest is one of which the medical profession can be justly proud.

MUSEUM OF MEDICAL PROGRESS OPENS IN PRAIRIE DU CHIEN, WISCONSIN

The Wisconsin Museum of Medical Progress, designed to carry historic and modern stories of medicine to the public, opened September 1, 1960, in Prairie du Chien, Wisconsin. A project of the Charitable, Educational and Scientific Foundation of the State Medical Society of Wisconsin, the museum is being financed by the contributions of physicians and other interested persons. It will be operated by the State Historical Society of Wisconsin. The museum is housed in the restored military hospital of Old Fort Crawford. It will tell medicine's story in a series of thirty-four displays and exhibits.

One series of exhibits traces medicine from the days of Indian cures to the "horse and buggy" doctor of the early twentieth century. A second series concerns Dr. Wm. Beaumont's contribution to medicine—treating an Indian guide with a gunshot wound and conducting experiments on digestion, the results of which provided the "basis of modern understanding of the physiology of digestion." A third major theme traces the development of medicine from the days of early quackery and "diploma mills" through the consequent establishment of the State Medical Society and the American Medical Association and the development of medical education.

On the basis of work started in 1931, the State Society, in 1954, established a Section on Medical History to begin collecting materials for the museum.

CLINICAL PARTY CONFERENCE

(Comparative Case Studies)

Patient 1	Patient 2

Chief Characteristics

Promotion of a trend, certain to terminate in socialism or a totalitarian welfare.	Preservation of controlled, competitive, free enterprise or the essence of Democracy.

Family History

1. Professed champion of the minorities.	1. Advocate of individualism, prudence, industry, ability, higher education, and all their rewards for members of all races and religions—the mainstay in the American Way of Life.
2. Power through appealing to the "less fortunate", those who work for a living.	2. Compassion and care for the truly unfortunate through aid to and control on the local basis (with free choice of physician).
3. Monopoly and centralization of government or maximum nationalization.	3. Decentralization of government or spread of authority to the states.
4. Generous with the people's monies probably to the degree of bankruptcy—(Khrushchev's favorite party).	4. Pay as you go program or fiscal responsibility.
5. Soak the greedy, glutted rich (incomes $675.00 a year and up plus "hidden taxes" and spiralling prices for every one).	5. Spare the goose that lays the eggs of gold.
6. Quick rewards through share the wealth programs for the "worker" eventually at a cost of a loss of personal dignity and human rights.	6. Success of individuals through rendering better competitive service or creative ability which has given us an unprecedented prosperity never experienced by man.

Present History

(pertaining to medicine)

1. Promotion of enforced governmental "free" medical care. (a) Wagner-Murray-Dingell Bill. (b) Murray-Dingell Bill. (c) Forand Bill. (d) Humphrey Bill 2009 (e) Any "foot-in-the-door" bill.	1. Opposition to all legislation leading to socialization of medicine.
	2. Proposes Mills bill (H.R. 12580 AMA approved) health care for the near needy elder citizens.
	3. Promotion of voluntary choice of private, competitive insurance for both medical and hospital services. (a) In this decade has temporarily turned the tide of a nation headed for governmental medicine. (b) Seventy million people have chosen private medical care insurance coverage.
2. Advocates of "free" medical care of non-service connected illnesses of veterans and their families.	4. Little opposition or action on non-service connected illness.

Predicted Sequelae

1. Complete socialization of medicine.
   (a) The greatest catastrophy ever to befall the people and physicians.
   (b) Monopoly of medical service and hospitalization by government.
   (c) Precipitous decline in quality and quantity of medical school student applicants (presently being experienced because of instability and anticipation).
   (d) Stagnation and slow deterioration of medical service.
   (e) "The government owes me a living" attitude.
   (f) Loss of present physician-patient relationship.
   (g) Limited choice of physician.
   (h) Layman control of physicians and patient care.
   (i) Limited salary but maximum security for physicians.
   (j) Deluge of demands for care of minor complaints.
   (k) An overwhelming cost to every wage earner for mediocre medical care and armies of government bookkeepers.
   (l) Regimentation of physicians by government and labor union policies: 40 hour week, 5 P.M. curfew, promotion by seniority rights or political skills, "feather bedding", strikes (Norway, England), intrinsically controlled limited service, closed shop (English panels), healing cult equality.
2. Gain control of medicine then—complete socialization will be easy (a Marxism). Result—"Cradle to grave" care of the people.
3. "England will not be conquered but will legislate herself into communism"—Carl Marx. How about the U.S.A.?
4. Road back to health will be long and arduous, indeed if health seems worth the effort to those who retain a spark of individualism.

1. Ever greater competition in rendering of private medical services by individual physicians, insurance companies and hospitals.
   (a) May the best physicians, insurance companies and hospitals prosper.
   (b) No interference with incentives to individual growth of 170,000 + physicians, many private insurance companies, pharmaceutical firms, and private hospitals.
   (c) Ever increasing improvement in physicians' training and quality of practice as a result of the experienced and inspired control by physicians using phenomenally successful methods, i.e., by way of national, State, County and hospital medical groups or "Organized Medicine".
2. Continuation of the acceleration of improvement of medical care of the ill and the prevention of illness in the healthy.
3. Maintenance of independence and dignity of the people plus a free choice of the best and least expensive medical care.
4. "Liberty is from the people." They must be in a position to regulate government and control its power.

Treatment

Doctor, do not permit Democracy to destroy its most precious possession, controlled free enterprise in the practice of medicine. The November elections will probably determine the future of medicine in the United States.

Suggestions: (1) Correct the apathy and lack of information among your patients, friends and legislators; (2) Vote on the issues at stake; (3) Send your substantial check in the name of the party of your choice.

DFL State Control Committee Headquarters, 6 East Franklin Avenue, Minneapolis, Minnesota.

Minnesota Republican Finance Committee, Northwestern Bank Bldg., Minneapolis 2, Minn.

A.H.W.

Opinions pro and con concerning the November election are welcome.

CLINICAL DIAGNOSIS OF MITRAL INSUFFICIENCY

Renewed interest in the diagnosis of mitral insufficiency has been generated by the open heart surgeons who now include repair of this defect in their repertoire. Precise diagnosis has become crucially important. When a combined lesion of the mitral valve is suspected, the surgeon must know which is predominant. If he believes the dynamic defect is stenosis, he very likely will elect a closed procedure. Under the circumstances, if his intra-atrial examining finger encounters the significant jet of severe mitral insufficiency, he may be forced impotently to retreat since today repair of insufficiency demands visualization of the valve. Conversely, he cannot indiscriminately use open surgery when the chief lesion is stenosis, reparable by safer closed procedures.

Alone of the heart valves, the mitral must withstand the systolic pressure of the contracting left ventricle. The pressure to be contained requires a complicated system of supports for the frail valve surfaces. The two leaflets supported by the stays of the chordae bear a resemblance to a double sail rigging with the anterior (aortic) leaflet serving as the important mainsail.

Insufficiency may result from (1) a congenital defect typified by the split valve of atrio-ventricular canal; (2) infection, such as rheumatic, subacute bacterial and, perhaps, brucellosis; and (3) insufficiency due to miscellaneous causes. Great enlargement of the left ventricle disturbs the mitral valve by dislocating the papillary muscles and attached chordae tendinae. Rarely may a myocardial infarct rupture a papillary muscle, or trauma sever one or more chordae, producing extreme insufficiency. Increasing in importance is the iatrogenic mitral insufficiency following surgical relief of mitral stenosis.

There is little in the history of the patient to differentiate insufficiency from other forms of mitral disease. Weakness may be more prominent than dyspnea. The "mitral facies" with the thin, pinched features, blue lips, and lilac cheeks is a late and striking manifestation. Left ventricular enlargement characteristic of mitral insufficiency produces a heaving impulse displacing the apex laterally and downward. The murmur typically is loud, low pitched, pan-systolic, heard principally at the apex and transmitted to the axilla. The variations from the typical are numerous. The pitch can be low or high, occasionally "screaming," the "sea-gull" sound. A thrill may be present with the loudest, lowest pitched murmur. The location is variable, the murmur often being well heard along the left border of the sternum. Finally, the intensity may be diminished to the point where the systolic murmur is entirely inaudible. The usual association of mitral insufficiency with stenosis means that often presystolic and usually mid-diastolic murmurs can be found. The accentuated sound of mitral valve closing (loud M1) and the sound of valve opening (opening snap) may be heard in insufficiency when one leaflet, particularly, the posterior remains mobile. As in mitral stenosis, pulmonary hypertension appears and a loud P2 occurs. Atrial fibrillation is also common.

The electrocardiogram, with its predominant right strain pattern, is helpful in differentiating mitral stenosis. Mitral insufficiency has a less typical pattern with both right and left abnormality. The chest roentgenograms in various positions, with a barium-filled esophagus, will show enlargement of both ventricles, a large occasionally giant left atrium and calcification of the mitral valve. Prolonged arm-to-tongue circulation time here is largely a function of the increase in central blood volume. Right and left heart catheterization, with pressure studies and dye dilution curves, are helpful, though not as definitive as in mitral stenosis. Angiography is less valuable but may serve to differentiate the uncommon atrial myxoma.

The differential diagnosis must evaluate the systolic murmur. A murmur of no cardiac pathologic significance must first be ruled out. Such a murmur is usually less than grade III intensity, not heard throughout systole, often disappearing on exercise or with change of position. It is associated with no other evidence of heart disease. Concomitant fever, infection, hyperthyroidism, or anemia may suggest that turbulent flow with high cardiac output is the cause of a murmur not associated with valvular difficulties. In the presence of rheumatic fever, a systolic murmur at the apex must be considered to be mitral insufficiency until proven otherwise.

Patent ductus arteriosus with a systolic murmur, interventricular and interatrial defects are the congenital diseases most often confused with mitral insufficiency. Aortic stenosis, with its murmur occasionally heard at the apex, is a trap for the

unwary. Peripheral signs of aortic stenosis are helpful. Demonstration of aortic valve calcification by x-ray, particularly by cinefluorography with the image intensifier, is diagnostic.

The chief right-sided lesions to be differentiated are pulmonary stenosis and involvement of the tricuspid valve. Here the peripheral evidence of expansile liver and pulsating veins are of diagnostic consequence. An excellent recent review of mitral insufficiency can be found in "Symposium on Mitral Insufficiency," (Mayo Clinic Proceedings, 33:497-534, October, 1958).

Reuben Berman, M.D.

CLINICAL DIAGNOSIS OF MITRAL STENOSIS

In the early days of penicillin, the story was told of a hospital where patients, on admission, were put into a ward and treated with penicillin for three days. If they were still ill at the end of that time, they were examined to find out what was wrong with them. In the present-day popularity of the cardiopulmonary laboratory, with the right heart catheterization, left heart catheterization, Gorlin formulae, and dye-dilution curves, many doctors forget that the routine examination of the patient is still the most important method for making the diagnosis in rheumatic heart disease. Cardiac auscultation remains the single most important method of examination. This, combined with a good history and physical examination, roentgen studies, and an electrocardiogram still gives most of the answers. Much of the data obtained by laboratory procedures can be predicted from the clinical examination. This is not to minimize the importance of laboratory procedures, for it is through their use that our clinical acumen has been and is being extended so that we can anticipate what the laboratory procedures will show.

The characteristic apical, rumbling, middiastolic murmur is the mainstay in the diagnosis of mitral stenosis. If this murmur is moderately loud or prolonged, mitral stenosis is almost certainly present. If, at a regular rate of below 90, the middiastolic murmur ends with a presystolic murmur, there can be little question about the presence of mitral stenosis. Next of importance is the presence of an opening snap of the mitral valve. This, however, is not always present and is not necessary for the diagnosis. An accentuated first heart sound is usually associated with the opening snap. There are a few conditions where a rumbling, middiastolic murmur may be present without mitral stenosis. These can usually be separated from the mitral stenosis if they are considered: (1) In congenital heart anomalies associated with increased flow across the mitral and tricuspid valves, a rather short middiastolic murmur may occur. The associated findings in these cases usually give a clue to the diagnosis. (2) The murmur of tricuspid stenosis is similar to that of mitral stenosis but is closer to the sternum. Mitral stenosis is usually also present. (3) Patients with fairly marked aortic insufficiency, and occasionally patients with large left ventricles due to other causes, may have a middiastolic and even presystolic murmur. Here the associated findings again alert one to the diagnosis. (4) Marked mitral insufficiency may be associated with a middiastolic murmur. Recognition of this condition is most important and will be considered in a moment.

Having decided that mitral stenosis is present, the questions that must be answered are: How tight is the mitral stenosis, and how flexible is the valve? The following considerations will usually decide whether the stenosis is tight or not:

(1) Generally speaking, a loud murmur, or one of long duration, is almost certainly associated with a tight mitral stenosis. The intensity of the murmur should be judged at a normal heart rate and not after exercise. On the other hand, a tight mitral stenosis may be present without a loud murmur and at times with almost no murmur. When the stenosis is very marked, the murmur may actually be faint or inaudible because of the marked decrease in flow through the valve. (2) With a tight mitral stenosis the patient must have a definite decrease in ability to exert. Women will often say that they are not short of breath, but, on the other hand, will admit that for years they have been limiting their activity so that they do practically nothing. Men, on the other hand, are forced to make a living and will get into difficulty with valve openings which are much larger than those in women. The greater body size of the men also accounts for the fact that men have trouble with valves which women could easily get by on. (3) Left auricular enlargement,

From the Cardiopulmonary Department of General Rose Memorial Hospital.

as determined by x-ray and electrocardiogram, is an important clue to the tightness of the stenosis if, by auscultation, one can rule out an important degree of mitral insufficiency. (4) If auscultation does not show too much mitral insufficiency, an increased pulmonary artery pressure indicates a tight mitral stenosis. The pulmonary artery and wedge pressures that will be found on catheterization can be very closely predicted in these patients on the basis of the clinical findings. This is done by correlating several factors: the size of the pulmonary artery, the size of the left auricle, the intensity of the pulmonic second sound, and the evidence of right ventricular hypertrophy by x-ray and especially on the electrocardiogram.

The amount of scarring and deformity of the valve can be predicted with good accuracy by the following factors: (1) A sharp high-pitched first heart sound indicates a valve that is mobile. As the valve loses its mobility the sound becomes dull and is diminished in intensity. (2) The presence of an opening snap of the mitral valve also indicates a mobile valve. Although a valve may be mobile enough to produce a loud first sound and an opening snap, the valve may be quite thickened and leathery. (3) The older the patient the more likely the valve is to be thickened and have some calcium in spite of the presence of an opening snap and a loud first heart sound. (4) When there is an appreciable degree of mitral insufficiency as determined by auscultation, the valve is much more likely to be a poor one for operative intervention than when there is no mitral insufficiency. (5) The presence of very much calcium on the valve, as determined by fluoroscopy, is also likely to indicate a badly scarred valve.

How does one interpret the presence of the murmur of mitral insufficiency when it appears that a mitral stenosis is present? (1) When evidence for a tight mitral stenosis includes the presence of an opening snap of the mitral valve and a loud first sound, the murmur of mitral insufficiency is usually not of great importance and can be ignored, even when it is fairly loud. (2) When the presence of a tight mitral stenosis is indicated by a moderately loud or loud diastolic murmur, but there is a dull first heart sound and no opening snap of the mitral valve, then the murmur of mitral insufficiency indicates a scarred valve with a fixed opening. A murmur of mitral insufficiency in these circumstances may be loud, even when the valve opening is only one square centimeter in diameter. (3) When the murmur of mitral insufficiency is loud and associated with a third heart sound rather than an opening snap of the mitral valve, and when the middiastolic murmur is rather short, then the mitral insufficiency probably predominates and the stenosis is not of an important degree.

A last word regarding the patient whose primary clinical finding is that of a marked tricuspid insufficiency with a loud, high-pitched systolic murmur which is maximum between the apex and the left sternal border: The tricuspid insufficiency is often the end result of a tight mitral stenosis, and the evidence of the mitral stenosis may be only a faint, middiastolic murmur heard in the anterior or midaxillary line. Recognition of these patients is important, because surgery often gives dramatic results.

"CANDY STRIPERS"

Some 150,000 teenagers are busy these days proving that adolescence is not necessarily a time of delinquency. They serve as volunteers in approximately 5,500 American hospitals.

Sometimes called junior aids, "volunteens," or "cartwheelers," they are usually known as "candy stripers." Their duties range from counting linen to feeding patients.

In addition to providing assistance in the hospital, the teenage program serves as a teaching procedure, according to Mrs. Palmer Gaillard, Jr., Mobile, Alabama, chairman of the American Hospital Association's Council on Hospital Auxiliaries and vice president of the board of trustees of the Mobile Infirmary.

It acts as a stimulant for recruitment into nursing and other health careers, and it helps teach future citizens about hospitals. "Out of teenage volunteers come adult volunteers and hospital board members," she said.

Teenage volunteers ideally are between the ages of sixteen and eighteen, although those as young as fourteen may serve with careful supervision. Both boys and girls work at such jobs as arranging flowers, supervising children's play, typing, waiting on tables, carrying messages, assisting in the library, preparing occupational and physical ther-

apy material, reading to patients, sorting mail, and acting as escorts.

Many of the hospital programs are arranged through school faculty advisors and vocational counsellors, placement directors of metropolitan volunteer bureaus, and leaders of scout troops, 4-H clubs and church groups. The teenagers are members of the organized volunteer department or service of the hospital, reporting to the person in charge of that department. All undergo initial training periods.

The importance of the teenage program was pointed up in 1958 when Governor Price Daniel of Texas commended the Candy Stripers of the Baptist Memorial Hospital, San Antonio. He said:

"In our justified concern over the rapid increase in juvenile crime . . ., we often overlook the good work being done quietly and effectively by American youth. . . . High on the list of such efforts is the commendable and constructive work of the 150 girls and boys, between the ages of fourteen and seventeen, comprising the Junior Auxiliary to the Baptist Memorial Hospital of San Antonio. . . ."

And a Boston teenager commented:

"As a junior volunteer I was able to get out of my own little world and meet a much broader world. I was able to feel needed and learned to accept many things. . . . I am grateful to have had this chance of serving others."

THE COUNTRY DOCTOR AND OUR PROSPEROUS FARMING COMMUNITIES

The time has come to bury the fake concept of the lovable, romantic picture of the country doctor rushing through hail, snow and sleet to deliver a baby by the light of a kerosene lamp, or still worse, to perform an emergency appendectomy on the kitchen table.

The modern doctor in our prosperous farming areas is more likely to work in a very modern, specially built clinic, with all of the necessary equipment that many city practitioners would envy. The old dingy office over the drug store is just as out of date as the horse and buggy. But the fake, even if romantic, concept still lingers on, and is causing our young men to overlook a wonderful satisfying field of practice—a field both professionally and monetarily satisfying.

It would be well to weigh the stress of competition, the maneuvering to get on a hospital staff with all the rules and restrictions put in his way—the traffic and parking irritations on one hand against the advantages on the part of a practice in the center of a prosperous farming community.

In the southern part of Minnesota we have a county about 25 miles by 35 miles and with a population of 25,000. This is served by seven active doctors. These figures alone will show that a newcomer would be welcomed by the doctors as well as the people. The community hospitals would welcome him with open arms and permit him to do anything that he can do properly.

Some towns have built modern doctors' offices, well equipped and offer them to the proper men at terms which cannot help but assure financial success. The towns are located on well-paved highways open the year around. There are good schools and churches for agreeable family living. The communities have become aware of the problems facing the doctors and are both willing and able to give him understanding support.

Why, then, is there such a shortage?

First and foremost, I believe we have not rid ourselves of the false concept of the country doctor mentioned above. But there is also a second drawback. This has been the effort of one man to carry the whole load on his shoulders. Modern practice requires laboratory and hospital facilities. The modern doctor requires and demands sufficient free time for family life, recreation and postgraduate work. This condition can be met only in a center large enough for two doctors working as partners.

Such offices (clinics if you will) can give around-the-clock service and still provide the doctor with the above-named private requirements. To do this, the partners must be equals, not senior and junior. If our young general practitioners would investigate the splendid opportunities offered, I am certain that many would find rich rewards in constructing a new country doctor image.

Hilmar R. Schmidt, M.D.

"While it is unlikely that the individual practitioner will see many cases of 'Jaguar chest' or 'Corvette hip.' the increasing popularity of smaller automobiles and the renaissance of the gearshift lever should be a warning to the clinician to be on the lookout for new musculoskeletal syndromes."—Jerome F. Strauss, Jr., M.D., J.A.M.A., May 28, 1960.

Public Health

ORAL POLIO VACCINE TRAITS IN MINNESOTA SUMMARIZED

The Minnesota Department of Health was first introduced to the Lederle-Cox strains of oral polio vaccine in 1957 when twenty-five infants (born to mothers immunized during pregnancy with two doses of Salk vaccine) ranging in age from four days to six months, were fed living attenuated poliomyelitis virus type I, type III, and type II at intervals varying from three to eleven weeks. Fourteen infants of less than two weeks in age were vaccinated against all three types of viruses. All demonstrated satisfactory antibody response at approximately two months of age.

When the orally vaccinated group was compared to a similar group of infants inoculated with Salk vaccine, the antibody response to the attenuated virus was found to be as good or better for types I and III, but poorer for type II. Evidence of spread to other members of the family, exclusive of the father, was determined by significant antibody rise or isolation of virus from the stool. Spread to siblings was 68 per cent for type I, 16 per cent for type II, and 60 per cent for type III. Illnesses attributable to the vaccine were not observed in the infants or members of their families.

Como Village

The next Minnesota study was conducted in Como Village, a crowded university housing development. A total of 551 persons (288 adults and 263 children), comprising 150 families, were given orally administered vaccine in capsules at three-week intervals in 1958.

The orally administered attenuated polio viruses used in the study were clearly effective as antigens for children. This effectiveness extended to all three types. When measured by a crude bettering of an original antibody titer of less than four, these viruses were effective in inducing such a change in approximately 85 to 90 per cent of the participants. The attenuated viruses used are like naturally occurring viruses in all respects, except that they do not produce clinical disease. Although the vaccine was less effective in adults, a trend was suggested in that the virus-fed group always had better conversion rates than the placebo-control group.

Grove East Village

While the monovalent capsules were being fed, Doctor Cox and his co-workers found it possible to pool the three types of attenuated poliovirus in a liquid form, thus making it possible to feed the three virus strains simultaneously in a single dose. Another study was undertaken in Grove East Village, a student housing development in St. Paul, to compare the effectiveness of the monovalent and trivalent vaccines.

Sixty-five families in Grove East Village participated—a total of 111 children and 108 adults. Half of the families received liquid monovalent vaccine at three-week intervals. The other half received two feedings of placebo followed by a third feeding of the liquid trivalent vaccine. The Grove East trials showed that the trivalent form did not act as effectively in producing antibodies and appeared especially weak for type II. The response in adults, as was the case in Como Village, was not as good as the response in children, although a definite trend toward positive responses was evident. The monovalent form used in these studies appears superior to the trivalent form in children, but there appears to be little choice when adults are involved. However, the trivalent vaccine seems to have enough efficiency and enough additional advantages to recommend it to the attention of workers in public health and preventive medicine.

St. Cloud Reformatory

A third study was conducted at the St. Cloud Reformatory in 1959. The objectives were to determine the effectiveness of trivalent vaccine to produce antibodies in relation to its ingestion before and after food; the effectiveness of feeding

trivalent vaccine in gelatin capsules (to bypass the pharynx), as compared to unencapsulated vaccine to produce antibodies; and the observation of pharyngeal recovery of poliovirus and occurrence of viremia.

The data evolved showed no significant difference in antibody response in the young male adults who participated, whether the vaccine was fed in liquid form or in gelatin capsules, or whether vaccine was fed before or after a meal. Pharyngeal infection occurred in a great majority of instances where the antibody titer was less than four for the virus type isolated. Viremia was detected only when the antibody titer was less than four for the virus type isolated. Virus was present in the pharynx in only two persons who swallowed the gelatin capsules, whereas virus was present in the pharynx in a large number of persons who drank the liquid vaccine. Viremia was detected in eight of ninety-five persons tested. None was ill at the time of viremia, and there were no illnesses reported which could be attributed to the vaccine in any of the participants.

1960 Field Trials

In 1960, Minnesota extended its study to include larger communities. These studies maintained the same standards as the smaller efforts. Every study was placebo controlled; every study was "double blind"; and surveillance arrangements were instituted. The feeding of 31,335 participants of all ages was completed on March 31 in Minneapolis. A total of 17,042 participants of all ages were fed in St. Paul, and feedings in Duluth numbered 21,700 persons of all ages. A study limited to preschool and school age children in Meeker, Kandiyohi, and Swift counties drew 16,000 registrants. Similar studies in Bloomington and St. Louis Park, Minneapolis suburbs, resulted in the feeding of 8,100 and 10,000 children, respectively. Thus, 104,288 persons received the oral vaccine (half getting a placebo). In all of the Minnesota studies, stool and blood specimens were collected at appropriate intervals. There have been no untoward effects or clinical illnesses which could be attributed to the vaccine.

AMERICAN HEALTH-CARE TEAM COMMUNICATIONS

Eugene N. Beesley, leading drug manufacturer, addressing the 1960 Michigan Clinical Institute, said that lack of understanding of the true facts of medicine and medical care "is casting doubt on the integrity of drug manufacturers, the efficacy of drugs, the ethics of the medical profession, and the quality of hospital treatment."

He said that the health-care team faces two big responsibilities. "To the extent that complaints and criticisms are justified, we must strive to make improvements.

"Our second responsibility must not be overlooked. The health-care team has done a better job in providing care for the sick than in telling its story to the public. We must do a better job at public relations.

Beesley said that drug prices are widely believed to be "high" or even "too high." "But too high in relation to what?" he asked. "Are the prices paid by consumers too high in relation to the benefits received? Have drug prices risen out of proportion to other commodity prices?

"There is certainly no evidence of an inordinate increase in retail drug prices. In fact, according to Dr. Jules Backman, professor of economics at New York University, Americans today would be paying a billion dollars a year more for drugs if the price of medicine had gone up as much as the total cost of living since 1939."

Total direct consumer expenditures for drugs increased from $1,466,000,000 in 1948 to $3,261,000,000 in 1958. Annual expenditures per capita increased from about $10 to about $19.

"But these increased expenditures for medicine do not necessarily reflect increased prices," he said. "They can and do reflect increased consumption. The principal reason for higher consumer expenditures for medicines is simply that more beneficial medicines are now available to the consumer than ever before in history.

"A second point of misunderstanding centers around average prescription price.

"This figure is derived simply by dividing the total dollars spent for prescriptions in a given year by the total number of prescriptions.

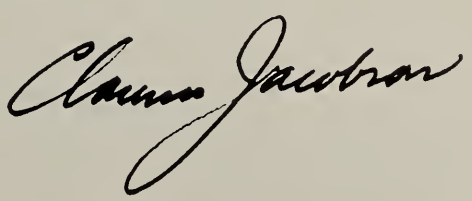
"On this basis, the consumer who paid $1.51 for the average prescription ten years ago will pay approximately $3.00 today.

"But this yardstick," he said, "is also virtually useless as a sound measurement for drug pricing performance, for it compares totally different things. The average prescription today involves products, processes, and benefits which did not exist in 1948.

"Comparing average prescription prices over a period of years is like comparing prices of a one-engine plane of thirty years ago with a Boeing 707 jet transport. You would hardly conclude that the price of a 707 jet is too high because it costs more than Lindbergh's *Spirit of St. Louis.*"

President's Letter

"LIFE THROUGH MEDICINE"



"Life through Medicine" was the theme adopted by the Council on Scientific Assembly for its 109th Annual Meeting at Miami Beach . . . a program dedicated to the student of medicine, the American physician, who in continuing his post-graduate medical education does so for the specific purpose of bringing to his patient the newer advances in medicine, thereby adding to the "two score and ten" of a short generation ago.

Approximately 9,000 physicians were in attendance together with an equal number of guests and auxiliary members, bringing the total close to twenty thousand. Preparing 290 scientific and 275 industrial exhibits represented a formidable task. The use of improved audiovisual means of presenting medical programs was utilized to the fullest. A complete course on body fluids was offered. The lectures, medical motion pictures and television programs were correlated to give complete coverage of the major problem diseases. The hundreds of participants were truly authors of this year's program which was in itself a textbook of medicine.

The 209-member House of Delegates, the policy-making body of the AMA, held its deliberations throughout the week in the Americana Hotel. The problems facing organized medicine today were reflected in the forty-six resolutions presented together with the nineteen referrals for supplementary reports of the Board of Trustees.

I refer you to the June issue of Minnesota Medicine news page, in which Mr. Brunn has summarized the proceedings setting forth the AMA's statement on the health care for the aged. In addition, the Board of Trustees was urged "to initiate a non-partisan open assembly to which all representative groups are invited for the purpose of developing the specifics for a sound approach to the health service and facilities needed by the aged, and that thereafter the American Medical Association present its findings and positive principles to the people." Also that "the AMA increase its educational program regarding employment of those over sixty-five; emphasizing voluntary, gradual, and individualized retirement, thereby giving these individuals not only the right to work but the right to live in a free society with dignity and pride."

Returning from the annual convention leaves one with a feeling of a rewarding experience. Witnessing the portrayal of scientific advancements and utilization of allied professions in the advancement of medical progress cannot help but fill the practicing physician with wonder and pride—wonder at the fact of accomplishments and pride knowing that all this is available to his patients. This situation is not duplicated elsewhere in the world today. Our endeavors to maintain these high standards continue in the halls of Congress to keep our profession free. Continued sustained effort will always be our heritage.

MINNESOTA PHYSICIANS URGED TO REPORT PROMOTERS OF ILL-ADVISED HOSPITAL PLANNING

Increased concern has been expressed by a number of Minnesota physicians with the critical problem of the ill-advised hospital planning in some small communities as well as in the suburban areas adjacent to the large metropolitan and urban centers in Minnesota. It has been reported that certain individuals with special interests in the promotion of hospitals, through the medium of fund raising and other devices, have approached suburban and rural communities encouraging the construction of small hospitals where previous surveys appear to indicate that the area is not of sufficient size to justify the construction and operation of such hospitals. In addition, others have proposed small facilities to provide a few beds for a limited maternity service and minimum medical services.

This can only result in a lowering of the quality of services in this as well as in adjacent hospitals, since occupancy rates in all surrounding hospitals usually decline when new beds are placed in operation elsewhere. The argument is frequently used that the costs in such small institutions are less than in a larger and more complete general hospital, whereas actually the services rendered are considerably below what is accepted today as complete and adequate hospital care.

Promoters Lack Qualifications

The Council of the Minnesota State Medical Association, on February 24, 1957, on the advice of its Maternal Mortality Committee, warned against the development of such limited hospital services and the associated potential increase in mortality. At the same meeting, the Council also endorsed the action of the State Board of Health relative to its refusal to license new structures as hospitals unless reasonable compliance is made with respect to both the quality of services and the extent and scope of the physical facilities to be provided.

The Minnesota State Medical and Minnesota Hospital Associations, as well as the American Medical and Hospital Associations, have constantly emphasized the importance of quality services and facilities in hospitals through compliance with the standards established by the Joint Commission on Accreditation of Hospitals.

Good Hospital Care Includes Many Factors

Hospital care today means the provision of trained and experienced personnel for services in administration, nursing, laboratory, x-ray, anesthesia, dietetics, medical records, physical and occupational therapy and other specialized services. The functions of the business office as well as the service departments, including the power plant, laundry, housekeeping and maintenance must be in capable hands if the hospital is to function properly and be administered economically. Small hospitals constructed without an adequate population base for continued support can only result in an unnecessary duplication of facilities and services in the area. Such small hospitals are too expensive, both in construction and operating costs to be justified, and adequate staffing of their services is next to impossible. The supply of trained personnel in the health field is extremely critical. Although there is a widespread interest developing in the recruitment of young people for careers in the health field, it will be many years before adequate numbers will be available to supply the demands. *A hospital is only as good as the quality of the personnel on its staff.* Adequate hospital services will not be provided unless hospitals are large enough to support both facilities and personnel.

Hospital Planning Requires Realistic Approach

Realistic hospital planning, therefore, means a careful study of the community and its surrounding trade area, including all adjacent hospital areas. sublimation of personal and community pride, a realization that the necessity for traveling a reasonable distance is of minor importance as compared to securing good hospital services to the end that there is provided an orderly pattern of care facilities of high quality. Any other action will result in economic waste in capital investment as well as in operation, a lowering of standards of care and

an inevitable loss of public confidence in the adequacy and quality of services provided in hospitals throughout the community, the state and the nation.

Association members who have reason to believe that, within the geographic area of their professional activities, a hospital is being planned, or promoted, that has not been discussed with qualified hospital authorities, are urged to bring this matter to the prompt attention of the Minnesota Department of Health, Division of Hospital Services, University Campus, Minneapolis 14, Minnesota.

Such action may help to avoid unnecessary and wasteful expenditures of much time and a great deal of money.

PROFILE OF A DOCTOR'S OFFICE IS GIVEN

Eight per cent of the physicians in the United States maintain more than one office. In population areas of more than 500,000 persons, 14.8 per cent of the doctors had more than one office; 6.3 per cent of doctors in cities in the ten to fifty thousand population range. In cities under 10,000 population, the number of doctors who maintained more than one office was estimated to be 6.9 per cent.

Specialists Most Likely to Have More Than One Office

Full time medical specialists more frequently than part time specialists or general practitioners have been found to maintain more than one office. For full time specialists the figure is twelve per cent, part time specialists, five per cent, and general practitioners 4.5 per cent.

Location of Doctors' Offices

Most doctors' offices are still located in downtown business districts. The estimated number is 39.5 per cent. For medical practices located in residential neighborhoods, the total is 25.4 per cent; shopping centers, 4.8 per cent; neighborhood business districts, twenty-four per cent and 6.3 per cent in all other localities.

Shopping Center Medical Practices Grow

According to a survey conducted by *New Medical Materia,* the number of physicians in shopping centers has jumped 153 per cent in three years. In 1958, the estimated total was 2,981; in 1959, the total increased to 4,025 and by 1960, the number rose to 7,536 or an estimated increase from 1959 to 1960 of 87 per cent.

Where Do Doctors Keep Their Offices?

Professional office buildings are used by 40.6 per cent of the physicians to house their practice; 10.7 per cent use group clinic buildings; 2.9 per cent hospitals; 8.6 per cent apartment buildings away from their residence; 17.1 per cent commercial office buildings; 18.0 per cent in their own homes and 2.1 per cent all other.

Pattern of the Doctor's Office

The average doctor's waiting room has seats for twelve patients. Only 4.2 per cent have no examination room; 20.5 per cent have one examination room; 32.3 per cent have two; 20.3 per cent have three; and 22.7 per cent have four or more examination rooms.

Washrooms

One washroom is the average for 61.5 per cent of the nation's doctors offices. Only 11.2 per cent have no washroom; 19.8 per cent have two; 4.8 per cent have three and 2.7 per cent have four or more washrooms.

Expansion Plans

It has been estimated that in 1960, 17.2 per cent or every sixth physician will improve his office space. Nine per cent will enlarge present space and 8.2 per cent will open a new office.

MEDICAL FEES SHOW UPWARD TREND

The national average for general practitioners fees in March, 1960, was $3.96 per office visit. This represents an increase of eighteen cents over the June, 1958, average of $3.78 per office visit.

House Calls

An average increase of 34 cents per physician's house call was noted since June, 1958. According to statistics prepared by the U. S. Bureau of Labor Statistics, in June, 1958, the average charge for a house call was $6.12. In March, 1960, it was $6.46.

Surgeons' Fees

During the same period, the national average fee for a tonsillectomy increased from $69.63 to $75.21. For an appendectomy, the average increase was $5.62. In June, 1958, the average fee for this procedure was $160.37 and in March, 1960, $165.99.

The Art of Medicine

PR

Carl H. Woyke, B.A.
Editor

DOCTOR, YOU ARE ALSO A CITIZEN

The Art of Medicine also includes the art of good citizenship. Physicians, as citizens, also have certain responsibilities toward the local community, the state, and the nation.

This is an election year. Americans will elect a President and Vice President; thirty-four Senators, also numerous Representatives, Governors and other state and local officials. Minnesota physicians, as citizens and members of the medical profession, have an important responsibility to help decide who these leaders will be.

To accomplish this, physicians must function as individuals through their county medical societies and the Minnesota State Medical Association. Individual members of the medical profession are encouraged to increase their active role as members of independent political action groups.

Basic Citizenship Responsibilities Given

The American Medical Association Field Service Division, which serves as a liaison between medical societies and the AMA, recommends the following seven "basics" of citizenship for the physician who wishes to take his civic responsibility seriously:

—The doctor's primary duty as a citizen is to be the guide and source of authority in all health matters relating to his community. This is an all-year-round civic responsibility, which his training and experience have qualified him to handle better than any other person in the community.

—The doctor should openly identify with the party of his choice, and vote regularly at all elections.

—The doctor should make an investment in democracy by contributing financially to the party of his choice.

—The doctor should encourage patients and others with whom he comes in contact to register and vote in all elections.

—The doctor should keep informed on candidates and issues and let others know where he stands politically.

—The doctor can help candidates of his choice by such means as displaying campaign literature in his waiting room.

—The doctor should devote as much time as his professional duties permit to work for good government and for the political party of his choice.

Medical Society Positions Defined

It is important to remember that as a corporate body, the medical society is seriously restricted by Federal law from direct political actions in elections and is prohibited from soliciting or contributing funds to any candidate or party in a federal election. However, a society is free to make its general political beliefs known to the public; to sponsor get-out-the-vote campaigns among its own members and the public; and to inform its members and the public on issues and candidates via such means as "know your candidates" meetings and distributing literature on candidates' voting records and views.

New Techniques Required

Medical societies interested in developing or supplementing better citizenship programs may benefit by observing programs which other organizations, such as the American Farm Bureau Federation, Kiwanis International, The American Heritage Foundation and the National Chamber of Commerce, have developed in the area of citizenship programs.

Citizenship programs which have proven successful, particularly in this an election year, include the National Chamber's Action Course in Practical Politics, Kiwanis International's Ballot Battalion and "CQ" program, and the American Heritage Foundation's "Register, Inform Yourself and Vote" program.

In numbers there is strength and much can be accomplished when a medical society joins forces with other community professional groups to explore a problem of national proportions. This is democracy at work seeking solutions to its own problems—these are groups of individuals using their trained talents in the service of the democratic values they cherish. More than ever before, our nation needs the trained minds of its professional people, no matter what their fields of excellence, to aid in discovering and applying solutions to the complex problems facing our rapidly changing society today.

Political Action Spurred by MD Training in Politics

Throughout the nation, increasing numbers of physicians have increased their effectiveness as workers for better government because they have been trained for their jobs.

Recommended as excellent training for this important job is the National Chamber of Commerce course in Practical Politics sponsored by local Chambers.

Frequently the formation of physician political action groups or committees has resulted in effective local action.

Normally these committees will function by concentrating their efforts in two directions: obtaining voluntary campaign contributions and conducting person-to-person publicity campaigns among friends, patients, relatives and other persons with whom they come in contact. Their message is what their congressman stands for and why he should be re-elected. In addition, the committee often invites members of the dental profession, insurance companies in the area as well as other doctors in the area to lend their support to the campaign.

Action Program Easy to Organize

The National Chamber of Commerce action program requires no political experience to organize and can be fitted into any society's program of activities. The National Chamber makes available all the necessary work materials for the course, including a discussion leader's manual which explains how to organize and conduct the nine workshop sessions on a weekly basis and contains a complete blueprint for the course. Course participants are provided with a set of eight pamphlets, each dealing with one important aspect of politics, such as: the individual in politics, political party organization, the political precinct, the political campaign, the political leader's problems. Participants also work on a series of case problems common to every community.

Individual physicians or medical societies interested in sponsoring this course in their community may write: Business Relations Department, Chamber of Commerce of the United States, 1615 H Street N.W., Washington 6, D. C.

For the graduate of the practical politics course or anyone interested in becoming active in politics, the Chamber has also developed an excellent "Checklist of Public Affairs and Legislative Opportunities" which lists a variety of ways in which the individual or organization may contribute to better government on every level.

Physician Good Government Action Vital

No longer can members of the medical profession regard politics and politicians as a necessary evil to be tolerated but kept at a safe distance from their daily round of activities. As medicine's future has been increasingly affected by legislative action and political decisions—as has every other sector of American life—physicians have been awakening to a long-felt need—to actively enter into political activities.

AMA's past president, Doctor Louis Orr expressed this new emphasis on political action: "A physician cannot, if he values this nation's high standard of medical care, divert his gaze from the social, economic and political issues which affect the practice of medicine." Said Dr. Orr, physicians have a duty to enter the political arena and present their case to the court of last resort, the American public.

Here's What Action Groups Can Do

Physician action groups can:

—Work to defeat Forand-type legislation and help to clarify public thinking on the whole issue of free enterprise vs. socialism as opposing systems by providing informed speakers to local organizations.

—Concentrate their efforts in an area in which they believe the physician can speak with authority—the health care problems of the aged; and find what the extent of the problem is locally in order to provide valuable information for the forthcoming White House Conference On Aging.

—Inform the public on social security legislation and its implications by distributing appropriate materials on this subject.

—Encourage the best possible candidates from both parties to run for public office and assist in their election.

—Encourage doctors at the local level to work for and actively support candidates of their choice.

—Solicit voluntary contributions to carry out these programs.

Good Government Action in Minnesota

When election day comes, Minnesotans will help to elect, in addition to a President and Vice President, a Governor and other State Officers, one United States Senator, nine Representatives and other local officers. President Eisenhower has said that in a democracy "politics ought to be the part time profession of every citizen." It is important that we remind ourselves that when people fail or refuse to exercise their responsibilities as citizens, government or other political groups will assume these responsibilities. Doctor, your professional life may well depend on how seriously you accept the challenge to exercise your rights as a citizen.

James A. Blake, M.D.
Chairman, Statewide Congressional (National Legislative) Committee

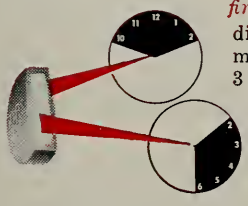
The Art of Good Citizenship

"Sometimes, when I have a running nose, I'd like to clear it with TRIAMINIC®— just to check out that systemic absorption business.



Reaches all nasal and paranasal membranes, huh?"

...and for humans with RUNNING NOSES...

You can't reach the entire nasal and paranasal mucosa by putting medication in a man's nostrils — any more than you could by trying to pour it down an elephant's trunk. TRIAMINIC, by contrast, reaches *all* respiratory membranes *systemically* to provide more effective, longer-lasting relief. And TRIAMINIC avoids topical medication hazards such as ciliary inhibition, rebound congestion, and "nose drop addiction."

Indications: nasal and paranasal congestion, sinusitis, postnasal drip, upper respiratory allergy.

Relief is prompt and prolonged because of this special timed-release action:

first— the outer layer dissolves within minutes to produce 3 to 4 hours of relief

then— the core disintegrates to give 3 to 4 *more* hours of relief

Each Triaminic timed-release Tablet provides:

Phenylpropanolamine HCl	50 mg.
Pheniramine maleate	25 mg.
Pyrilamine maleate	25 mg.

Dosage: 1 tablet in the morning, midafternoon and at bedtime. In postnasal drip, 1 tablet at bedtime is usually sufficient.

Each timed-release Triaminic Juvelet® provides:
½ the formulation of the Triaminic Tablet.
Dosage: 1 Juvelet in the morning, midafternoon and at bedtime.

Each tsp. (5 ml.) of Triaminic Syrup provides:
¼ the formulation of the Triaminic Tablet.
Dosage (to be administered every 3 or 4 hours):
Adults — 1 or 2 tsp.; *Children 6 to 12* — 1 tsp.;
Children 1 to 6 — ½ tsp.; *Children under 1* — ¼ tsp.

TRIAMINIC®

timed-release tablets, juvelets, and syrup

STOP *running noses* *and open stuffed noses orally*

Minnesota Blue Shield

Since Congress approved the Federal Employees Health Benefits Act last September, more than 55 per cent of the estimated 1,695,000 Federal workers who selected health benefits coverage from among the thirty-eight different programs chose Blue Shield as their medical care plan.

Under this act, Federal employees have the option of participating if they wish and are free to choose the health plans they prefer. The Federal government, as the employer, shares in the cost of this group coverage.

The preference for Blue Shield as the medical care plan was "an overwhelming vote of confidence in these community-oriented organizations," according to a spokesman for the National Association of Blue Shield Plans.

The Blue Shield spokesman noted that a breakdown of enrollment totals showed that government employees chose the high level-higher cost benefit program in preference to the low benefit-lower cost option, in a ratio of about four to one.

The high level benefit programs offered by other organizations were similarly preferred to the low cost-low level coverage. The Blue Shield spokesman said this indicated people were prepared to pay the additional price for broader forms of protection.

The choice exercised by Federal employees in selecting health benefit programs is especially significant because it represents the first time the element of free choice involving such a variety of programs has been exercised by so many individuals at one time.

"Neither group enrollment in industry nor individual enrollment campaigns on a community basis," the Blue Shield spokesman said, "can be compared with the Federal employee enrollment, and that is why the 'vote of confidence' for Blue Shield by these workers stand as remarkable evidence of the confidence the public has in Blue Shield organizations."

Minnesota Blue Shield will process claims for services rendered by Minnesota doctors to Federal employees covered by this nationwide plan.

In Minnesota approximately 15,000 Federal employees have enrolled in the Blue Shield plan. The rapid assimilation of so large a group presents a difficult administrative problem. The assignment of individual numbers, preparation of identification cards, and the various other administrative functions required for this processing will take some time. It is possible, therefore, that during the next few weeks, Federal employees may seek (and be entitled to) your professional services under this plan even though they have not yet received Blue Shield identification cards.

In order to facilitate the prompt payment of claims in this event, participating physicians are asked to submit the following information to Blue Shield headquarters:

1. The full name of the patient.
2. The specific office, department, and federal agency of his employment and the address.
3. The type of coverage (whether the patient is enrolled under the high or low option of the Blue Shield Federal group plan. The high and low options are comparable to Plan A and Plan B of the conventional group contracts.)
4. A brief description of the service rendered.

All new subscribers to the Federal group plan will soon have received their identification cards, and the inconvenience of operating without them will be a temporary one. The Blue Shield organization, meanwhile, will appreciate the cooperation of participating physicians in processing these claims in the above manner.

* * *

Minnesota Blue Shield is now sponsoring the radio series, "Doctor's House Call," featuring Dr. James Rogers Fox, on WCCO Radio, Minneapolis.

Doctor Fox, representing the Minnesota State Medical Association, has a large and loyal listening audience. His Monday-through-Friday programs are recognized as a significant contribution to public health education in Minnesota.

The five-minute programs are heard twice each evening, at 6:30 p.m. and 8:55 p.m.

* * *

Minnesota Blue Shield participating doctors as well as pharmacists throughout the state are lending valuable support to the Blue Shield program by displaying application folders for Blue Shield non-group contracts.

Coverage of non-group subscribers is an important aspect of the Blue Shield program and doctors and pharmacists, by making the application folders conveniently available, are helping to expand this coverage.

The Blue Shield organization urges both doctors and pharmacists to continue their support, which can do much to strengthen the position of voluntary medical care coverage in their areas.

SALUTENSIN™

Hydroflumethiazide • Reserpine • Protoveratrine A

An integrated multi-therapeutic antihypertensive, that combines in balanced proportions three clinically proven antihypertensives.

In each **SALUTENSIN** Tablet:

Saluron® (hydroflumethiazide)—
a saluretic-antihypertensive ..... 50 mg.

Reserpine—a tranquilizing drug with
peripheral vasorelaxant effects ..... 0.125 mg.

Protoveratrine A—a centrally mediated
vasorelaxant ..... 0.2 mg.

Comprehensive information on dosage and precautions in official package circular or available on request.

BRISTOL LABORATORIES • Syracuse, New York

For fast, complete treatment of vaginal infections

Problem is: she'll wait until discomfort is acute and then expect immediate relief. The answer is Trisert. Trisert preparations contain ALLANTOIN, an effective debriding agent which quickly dissolves heavy mucus often accompanying vaginal infections . . . METHYLBENZETHONIUM CHLORIDE, a quaternary germicide which removes unpleasant odors . . . SUCCINIC ACID, an aid in maintaining optimal vaginal pH . . . 9-AMINOACRIDINE HYDROCHLORIDE which has been included to supplement the bactericidal and trichomonacidal activity of other constituents. Treatment with Trisert Powder will control symptoms fast . . . usually within an hour . . . and provide effective initial treatment for 48 hours. After a second insufflation, the treatment is completed with at home use of Trisert Tablets which will generally bring the infection under complete control within 7 days.

Trisert

TRISERT TABLETS—Patient set, contains bottle of 30 tablets and special inserter. Bulk bottle of 100 tablets.

TRISERT POWDER—Available in 4 gr. individual treatment bottles. 12 to carton.

TRISERT POWDER INSUFFLATOR—Designed for use with Trisert Powder. Its use is urged for maximum efficiency.

DETROIT (MICHIGAN) EX-CONVICT POSING AS PHYSICIAN CONVICTED ON NARCOTIC CHARGE

On June 6, 1960 Arthur Jangochian, thirty-four, 13160 Greenlawn, Detroit, Michigan, was sentenced by the Hon. Irving R. Brand, Judge of the District Court of Hennepin County, to a term of ten years at hard labor in the State Prison at Stillwater, having been convicted of the crime of unlawfully having possession of a narcotic drug. On April 29, 1960 the defendant had entered a plea of guilty to an information charging him with that offense. However, after sentencing the defendant Judge Brand stayed the execution of the sentence on condition that the defendant remain outside of the State of Minnesota. Immediately before being sentenced by Judge Brand, Jangochian had pleaded guilty to a charge of having two prior convictions for felonies.

The defendant was arrested in Minneapolis on April 25, 1960, when he appeared at the Richter Rexall Pharmacy, 427 Cedar Avenue, to purchase twenty-four 1/16 gr. tablets of dilaudid, claiming that he was the son of a cancer patient for whom a Minneapolis doctor had prescribed the drug. A short time before Jangochian entered the drug store, he had placed a telephone call there stating he was a Minneapolis physician, giving his name, and ordering the dilaudid for a "patient" who allegedly lived at an address on 19th Avenue South. The suspicions of the pharmacist were confirmed when he called the physician whose name the defendant had given and learned that no medication of any kind had been prescribed for the patient in question.

In a signed typewritten statement, the defendant admitted that he had arrived in Minneapolis from Detroit on the day before his arrest in order to visit a woman who worked in a Minneapolis night club and that he had made the telephone call to the drug store from her apartment. He also admitted that he was the owner of a small quantity of marihuana which was found in her apartment but he denied that the woman used narcotic drugs. Jangochian, who gave his occupation as a musician and a drummer, admitted to Judge Brand in court that he had been convicted as follows for unlawfully possessing narcotic drugs, both convictions being in Wayne County, Michigan, for violating state drug laws: May 20, 1953—sentenced to a one to four-year term at the State Prison at Jackson, Michigan; July 17, 1958—sentenced to serve a two to four-year term in the same institution. The defendant also admitted at the time of his arrest in Minneapolis that he was out of prison on parole.

PROFESSIONAL EDUCATION SEMINARS

The first in a series of Professional Education Seminars for physicians, dentists and nurses in Minnesota will be offered at Mankato this fall. The seminars will begin on Tuesday evening, October 18, and will meet for six consecutive Tuesdays through November 22, with classes running from 7:30 to 9:30. Meetings will be held at St. Joseph's Hospital in Mankato.

Communications

NEW UNIVERSITY OUT-PATIENT CLINIC APPOINTMENT SYSTEM

For many years, the University Out-Patient Clinics have accepted new patients for examination any weekday without advance scheduling. This policy has been followed on the assumption that better service could be provided by leaving the clinic doors "open," as it were, and being completely available and accessible at all times for referral. At times this has had the opposite effect and has resulted in disagreeable and expensive delays. It now seems clear that better patient care can be provided, and the needs of all concerned better served, if we schedule initial examinations.

Therefore, in contrast to our previous policy we are now sending patients specific advance appointments for examination. *This will not mean a wait or delay for appointments.* However, unless you indicate that it is desirable that the patient be seen immediately, he will be given a minimum of one week notice of his appointment to arrange for his clinic visit. (Patients who come without appointments will be seen, but obviously patients with advance appointments will be given preference.) Of course, patients with urgent or emergent medical problems will be seen without delay whether or not they have advance appointments. Indication of this on the medical referral or a phone call to Mr. Glenn Mitchell, the Director of Admissions, will expedite the patient's care in such cases.

As heretofore, *county patients* will be referred by their physician through their County Welfare Boards. As soon as the medical referral and County Papers for a new patient are received, the Director of Admissions will mail an appointment for a definite date and time to the patient. The referring physician and the County Welfare Department will both be notified of the patient's appointment date.

Part-pay, or *per diem patients,* which the physician refers here directly, should be scheduled for examination by writing or calling Mr. Mitchell, Director of Admissions. As soon as the medical referral is received an appointment will be mailed directly to the patient with a copy going to the referring physician.

Policies concerning private patients remain unchanged. Appointments for such patients are by direct referral by the patient's private physician to the individual staff physician or department.

The University clinic has always provided primarily a consultative kind of service for the patient and his physician (and at times the community). There will be no change in this function except that we expect to improve communication with referring doctors and speed the return of reports.

UNIVERSITY OF MINNESOTA MEDICAL SCHOOL

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

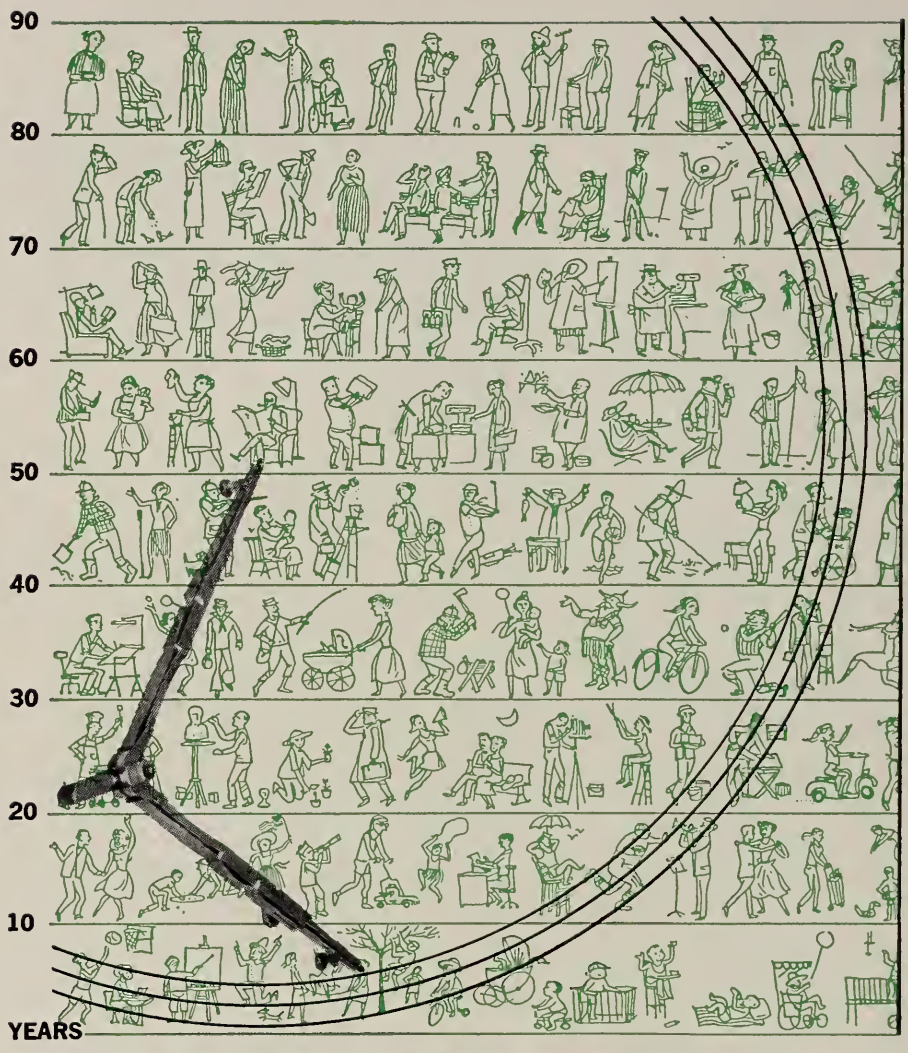
NEW REGULATIONS OF FOOD AND DRUG ADMINISTRATION

Stronger regulations to insure that physicians receive adequate information about the drugs they prescribe and to insure the safety of new drugs were proposed by the Food and Drug Administration.

The new regulations would:

1. Require sweeping changes in the labeling of prescription drugs. Virtually all prescription drug packages and printed matter distributed to physicians to promote sale of a drug would be required to bear complete information for professional use of the drug, including information about any hazards, side effects or necessary precautions.

FDA said that heretofore such fully detailed information has not been required in labeling when it was available in scientific literature, or, in certain cases, was available to the physician upon request. The only exception in the proposed regulations would apply to frequently used medicines that are commonly familiar to the doctor.



2. Provide that when safety requires, a new drug would be kept off the market until the manufacturer's representations regarding the reliability of manufacturing methods, facilities and controls have been confirmed by a factory inspection by the Food and Drug Administration.

Such an inspection would verify that the firm can insure the identity, strength, quality and purity of each batch of the drug, FDA said. Occasional inspections have shown conditions in manufacturing plants which were contrary to representations made by the manufacturer in his request for safety clearance.

Other proposed labeling changes would require drugs for injection and for use in the eyes to bear a quantitative declaration of all inactive ingredients. Labels of all prescription drugs would be required to include an "identifying lot or control number from which it is possible to determine the complete manufacturing history of the drug." Exemptions are permitted where there is insufficient label space provided the information is given on other parts of the drug package. All labeling bearing information for use of a drug would be required to have the date of its issuance.

FDA said the proposed labeling changes would correct a tendency on the part of some manufacturers to describe to physicians the merits of a drug without giving information regarding its hazards and the special precautions necessary for maximum safety and effectiveness.

Commenting on the proposed regulations, George P. Larrick, Commissioner of Food and Drugs, said:

"The large number of new medications has made it increasingly difficult for doctors and pharmacists to keep adequately informed about them. We are hopeful that the proposed regulations will improve the communication of vitally necessary information and bring about a general improvement in drug promotion practices. At the same time, they should furnish a basis for more effective government control where necessary."

Interested persons are invited to submit written comments on the proposed regulations to the Hearing Clerk, Department of Health, Education and Welfare, Room 5440, 330 Independence Ave., S. W., Washington 25, D. C., within 60 days from the date of publication in the Federal Register.

* * *

NOTE TO CORRESPONDENTS: The proposed regulations discussed above are published in the July 22, 1960, *Federal Register.*

PHARMACEUTICAL RESEARCH

The prescription drug industry reports it spent $197 million on research and development last year in the biggest privately financed assault on ill health in history.

The expenditure—16 per cent higher than in 1958—amounted to 7.8 per cent of the companies' pharmaceutical sales of more than $2.5 billion.

Dr. Austin Smith, president of the nationwide trade association of 140 ethical drug firms, hailed the expenditure as "a typically American example of the force of private enterprise at work for the betterment of humanity." The third annual survey of research activities of the industry in co-operation with the National Institutes of Heath disclosed, among other facts:

- Drug industry research spending in 1959 was $7 million more than the companies estimated a year ago that it would be.
- Over $18 million of the total was spent outside of pharmaceutical house laboratories in the form of grants and contracts to medical schools, hospitals, research institutes and other institutions.
- An estimated 100,200 chemicals, compounds and other substances were prepared, obtained and biologically tested by the industry in 1959 in its search for new and more specific medicinals.
- Of these substances, 36,600 were in the field of cancer chemotherapy. The second heaviest concentration was 28,200 substances pertaining to allergies and infectious diseases.
- The 140 producer members of the Pharmaceutical Manufacturers Association, responsible for more than 95 per cent of ethical drug production in the United States, estimate research and development spending of $214 million in 1960.

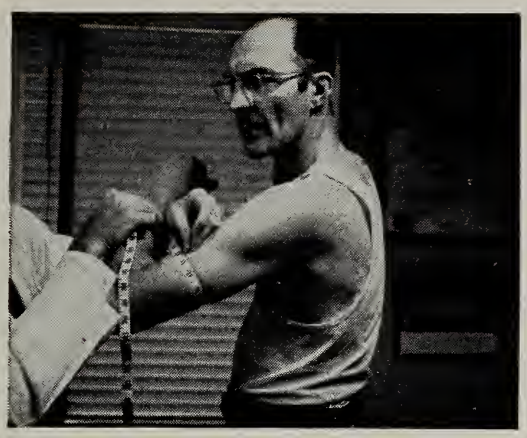
Q. *When you want to reduce serum cholesterol and maintain it at a low level, is medication more realistic than dietary modifications?*

A. *Maintenance of lowered cholesterol concentration in the blood is a life-long problem. It is usually preferable, therefore, to try to obtain the desired results through simple dietary modification. This spares the patient added expense and permits him meals he will relish.*



The modification is based on a diet to maintain optimum weight plus a judicious substitution of the poly-unsaturated oils for the saturated fats. One very simple part of the change is to cook the selected foods with poly-unsaturated Wesson. In the prescribed diet, this switch in type of fat will help to lower blood serum cholesterol and help maintain it at low levels. The use of Wesson permits a diet planned around many favorite and popular foods. Thus the patient finds it a pleasant, easy matter to adhere to the prescribed course.

Where a vegetable (salad) oil is medically recommended for a cholesterol depressant regimen, Wesson is unsurpassed by any readily available brand.

Uniformity you can depend on. Wesson has a poly-unsaturated content better than 50% . Only the lightest cottonseed oils of highest iodine number are selected for Wesson. No significant variations are permitted in the 22 exacting specifications required before bottling.

Wesson satisfies the most exacting appetites. To be effective, a diet must be *eaten* by the patient. The majority of housewives prefer Wesson particularly by the criteria of odor, flavor (blandness) and lightness of color. (Substantiated by sales leadership for 59 years and reconfirmed by recent tests against the next leading brand with brand identification removed, among a national probability sample.)

Dianabol: new, low-cost anabolic agent

By promoting protein anabolism, Dianabol builds lean tissue and restores vigor in underweight, debilitated, and dispirited patients. In patients with osteoporosis Dianabol often relieves pain and increases mobility.

As an anabolic agent, Dianabol has been proved 10 times as effective as methyltestosterone. Yet it has far less androgenicity than testosterone propionate, methyltestosterone, or norethandrolone.

Because Dianabol is an oral preparation, it spares patients the inconvenience and discomfort of parenteral drugs.

And because Dianabol is low in cost, it is particularly suitable for the aged or chronically ill patient who may require long-term anabolic therapy.

Supplied: *Tablets,* 5 mg. (pink, scored); bottles of 100.

Complete information sent on request.

Dianabol®
(methandrostenolone CIBA)

converts protein to working weight in wasting or debilitated patients

In Memoriam

JOE W. BAIRD

Dr. Joe W. Baird, Minneapolis, died July 19, 1960. He was fifty-five years of age at the time of his death.

Doctor Baird specialized in Anesthesiology and received his medical education at the University of Nebraska College of Medicine, Omaha, in 1930.

His internship was served at the University Hospital in Columbus, Ohio. His postgraduate work included two years at Hartford, Connecticut, Hospital. From 1931 to 1940, he practiced medicine in Arcadia, Nebraska.

He was clinical associate professor of anesthesiology at the University of Minnesota, Director of Anesthesiology at Abbott Hospital, Past President of the Minneapolis Academy of Medicine and of the Minnesota Society of Anesthesiology, and was a member of the American Society of Anesthesiology, Hennepin County Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, Ruth; one daughter; his mother, and two sisters.

JOHN SPENCER HAMLON

Dr. John Spencer Hamlon, Fergus Falls, died July 18, 1960. He was fifty years of age.

Doctor Hamlon was born in Lamberton, Minnesota, and received his preliminary education at John Marshall High School in Minneapolis and the University of Minnesota. He graduated from the University of Minnesota Medical School in 1935 and served his internship at Swedish Hospital in Minneapolis.

He was on the staff of the State Hospital in Fergus Falls, where he worked with patients in the receiving department.

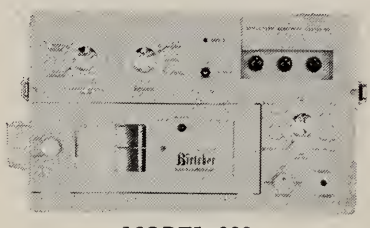
Doctor Hamlon was a member of the Park Region Medical Society, the Minnesota State Medical Association and the American Medical Association.

Survivors include his wife, two children and his mother.

JAMES T. LARSON

Dr. James T. Larson, medical doctor for the Swift Company, died September 9, 1960. He was fifty-six years of age.

Doctor Larson was born in Hartland, North Dakota, in 1904. He received his preliminary education from Donnybrook, North Dakota, High School and Grinnell College, Grinnell, Iowa. He was graduated from the University of Minnesota Medical School in 1929. He served his internship at Minneapolis General Hospital.



He was a member of Masonic Lodge No. 262 A.F.& A.M., Lake Wilson, Minnesota; Triune Chapter, Royal Arch, Pipestone, Minnesota, Ramsey County Medical Society, Minnesota State Medical Association, and the American Medical Association. He was a past master of the Masonic Lodge at Lake Wilson.

Doctor Larson is survived by his wife, his mother, two daughters, three sons, five sisters, two brothers and two grandchildren.

Woman's Auxiliary

SCHOOL OF INSTRUCTION HAS VARIED PROGRAM

The latest developments in National and State Legislation and Food Fads and Misinformation will be among presentations to be given at the 1960 Woman's Auxiliary School of Instruction, Thursday, September 29, 1960, in the Cardinal Room of the Curtis Hotel in Minneapolis.

Registration and a coffee hour will be held from 9:00 to 9:30 a.m. and the Business Session will be held from 9:30 to 10:00 a.m.

The Food Fads presentation will be introduced at 10:00 a.m. with the showing of the AMA sound film "The Medicine Man."

Dr. Robert D. Semsch, chairman of the Public Health Education Committee of the Minnesota State Medical Association, will point out the importance of an educational program of this type and explain how Auxiliary members can assist in the project.

A representative of the Minnesota Dietetic Association will explain the details of the state-wide program to combat food fads and misinformation. The Auxiliary will co-operate in this project sponsored by the Minnesota Dietetic Association and supported by the Minnesota State Medical Association. The project will include a series of programs featuring a showing of "The Medicine Man." In conjunction with the showing of the film throughout the state, a physician and a member of the Dietetic Association will be present to answer nutritional questions.

For the session on Legislation, the Committee has invited Mr. Charles Johnson of the Field Services Division of the American Medical Association, Chicago, to present the latest information about Federal medical legislation.

Dr. Les N. Dale, Red Lake Falls, chairman of the Public Policy Committee of the Minnesota State Medical Association, will speak about 1960 legislative trends on the state level.

The Luncheon, which is scheduled for 12:15 p.m., will conclude the program.

* * *

RAMSEY COUNTY AUXILIARY HOLDS FALL FASHION SHOW

The annual Fall Fashion Show and Luncheon of the Ramsey County Medical Auxiliary was held Monday, September 26, at the St. Paul Hotel in St. Paul. Mr. Engelson of Rosen-Engelson Furs presented an inspiring fashion show.

Mrs. Marcus Shelander was in charge of the arrangements and Mrs. Walter Carley was in charge of the models. Mrs. Donald Roach and Mrs. Louis Nelson handled the tickets and reservations.

The Physician's Diary

Canby physician, **Dr. L. J. Holmberg**, was honored on his eighty-fifth birthday and his fifty-two years of medical practice by residents of that town. A dinner at 6:30 p.m. was followed by a program.

* * *

The American College of Physicians has elected **Dr. Sidney O. Hughes**, of Winona, as an associate of the group. His election was approved by the Board of Regents of the College who met in San Francisco, following certification of his qualifications for membership and approval of his nomination by the College's regional governor.

* * *

Dr. John K. Butler, Cloquet physician, has been installed as chief of the medical staff of the Community Memorial Hospital in Cloquet. **Dr. R. M. Eppard** is the retiring chief of staff. **Dr. C. E. Norberg** was selected as chief of staff-elect and **Dr. L. B. Backus**, secretary-treasurer.

* * *

Clinton, Minnesota, has a doctor. He is **Dr. Carl E. Christenson**, a recipient of the Rural Medical Scholarship awarded annually by the Minnesota State Medical Association. Under terms of the Scholarship, Doctor Christenson must practice in a rural Minnesota community in need of a doctor for at least five years. The residents of Clinton raised money and built a Clinic for Doctor Christenson.

* * *

One of three University of Minnesota doctors receiving grants totalling $54,340 for heart research was **Dr. C. Walton Lillehei.** He received $33,000 for work on the development of new methods for cardiac surgery. The awards are part of over a million dollars granted by the Life Insurance Medical Research fund this year. They enable researchers to study normal heart function as well as heart diseases.

* * *

The Park Region Medical Center has announced the affiliation of **Dr. Cheng-En Lu** to its medical staff. **Doctor Lu** is a graduate of the West China Union University. His wife is also a physician and is on the staff of the Fergus Falls State Hospital.

* * *

Dr. John M. Burns has now become associated with the Oliver Clinic in Graceville. Doctor Burns is replacing **Dr. C. J. Swendseen** who has left for Washington, D. C., where he is taking a three year residency in radiology. Doctor Burns will be associated with **Dr. I. L. Oliver.**

* * *

The American Protologic Society has elected **Dr. John R. Hill** of the Section of Proctology in the Mayo Clinic to the Council of the group. Doctor Hill will serve a term of two years. The organization was formed in 1899 to promote the study of protologic diseases.

* * *

The *Miami Herald,* on June 17, published a feature article about **Dr. Louis A. Buie,** emeritus member of the Mayo Clinic, entitled "Meet Mr. Ethics." In the article, Doctor Buie is praised for his work on the doctor's code of ethics of the American Medical Association. He was in charge of revisions of the "Principles of Medical Ethics" which serve as a guide for physicians in the conduct of their practice. Dr. Buie retired from the A.M.A. Judicial Council at the Convention held in Miami after serving for fifteen years. He is now working with a new A.M.A. group called the Medical Disciplinary Committee.

* * *

A new surgeon has joined the St. Louis Park Medical Center. He is **Dr. Earl G. Yonehiro,** a much decorated World War II combat veteran . . . member of the famed 442nd Regimental Combat Team. He holds the Silver Star and Purple Heart with two Oak Leaf clusters. Doctor Yonehiro is a graduate of the University of Rochester, New York, and took special work at Harvard.

* * *

Dr. W. C. Heiam has been elected chief of staff of the Cook Community Hospital in Cook, Minnesota. **Dr. Floyd J. Swenson** was elected secretary. **Dr. W. S. Neff,** Virginia, and **Dr. J. A. Malstrom,** Virginia, were appointed to organize by-laws for the new group.

* * *

A member of the Minnetonka Clinic in Excelsior, **Dr. Roger S. Johnson** has resigned from his partnership in that Clinic to begin studying under a Surgical Fellowship awarded him by the University of Minnesota.

* * *

Tracy physician, **Dr. W. H. Valentine,** was honored at a reception in honor of his eighty-fifth birthday and sixty years of medical practice. Over 150 guests were present, including former and present nurses, their husbands and Tracy hospital board members and their wives. Doctor Valentine began his practice in Tracy in 1900.

* * *

Dr. C. P. Johnson, of Tyler, has announced that **Dr. Richard Engwall,** Ivanhoe, and **Dr. Mark Muesing,** formerly of Duluth, have joined him in the practice of medicine. Doctor Engwall is a recipient of the Rural Medical Scholarship and a graduate of the University of Minnesota Medical School. Doctor Muesing is also a graduate of the University of Minnesota.

SQUIBB *Squibb Quality—The Priceless Ingredient*

'ENGRAN'® AND 'TERM-PAK'® ARE SQUIBB TRADEMARKS

Dr. William R. Hilgedick has joined the staff of **Dr. Ralph Papermaster** in Two Harbors. Doctor Hilgedick has served for two years in the U. S. Army Medical Corps in Formosa and is a graduate of the University of Minnesota Medical School.

* * *

The new doctor in Pine Island is **Dr. John Hetzler.** He is a graduate of the University of Minnesota Medical School and comes to the community of Pine Island from Mandan, North Dakota.

* * *

Dr. Homer H. Russ, formerly of St. Paul, has opened offices for general practice in the former Bowler Insurance Building in LeCenter. Doctor Russ is a graduate of the University of Minnesota Medical School and has recently completed his internship at Bethesda Hospital in St. Paul.

* * *

The Lakeland Medical Center of Willmar once again has the services of **Dr. Robert V. Hodapp.** Doctor Hodapp has been on leave of absence since July, 1958. He has been engaged in a pediatric residency training at the University of Minnesota and will limit his practice to pediatrics in Willmar.

* * *

The Bemidji Clinic has announced the addition of **Dr. Earl Gregoire** to its staff as a resident physician. Doctor Gregoire has replaced **Dr. George H. Spurbeck** who resigned after two years at the Clinic to accept a position as senior medical officer at the Veterans Administration Hospital in Fargo, North Dakota. Doctor Gregoire is a graduate of the University of Oregon Medical School. He will specialize in the practice of obstetrics and gynecology.

* * *

Dr. James R. Schuft is now in the practice of medicine with **Dr. Robert M. Watson** in Morris, Minnesota. Doctor Schuft is a graduate of the University of Minnesota Medical School.

* * *

Dr. William C. Bernstein, Director of the Division of Proctology at the University of Minnesota Medical School, recently addressed the Southwestern Minnesota Medical Association at Worthington on "Common Proctologic Problems." On June 23, he addressed the Wisconsin Academy of General Practice in Madison, Wisconsin, on "Present-Day Concepts of Polyps of the Rectum and Colon."

* * *

Dr. Edmund B. Flink, formerly of the Veterans Administration Hospital in Minneapolis, has accepted an appointment as Professor of Medicine and Chairman at the new West Virginia University in Morgantown, West Virginia. Doctor Flink began his duties the first of this month.

* * *

Belle Plaine, Minnesota, has recently acquired two new doctors. They are **Dr. Roger Hallgren,** who has just completed three years as a Captain in the Air Force Medical Corps, practicing in association with **Dr. H. M. Juergens,** and **Dr. B. D. Kaiser,** of Minneapolis, who

1400 Harmon Place, Minneapolis 3, Minnesota

has just completed his internship. He is moving into the office of the late **Dr. C. J. Olson.** He will be associated with two Le Sueur doctors in the formation of the Minnesota Valley Medical Clinic. Doctor Hallgren is a graduate of the University of Minnesota Medical School and Doctor Kaiser graduated from Creighton Medical School at Omaha.

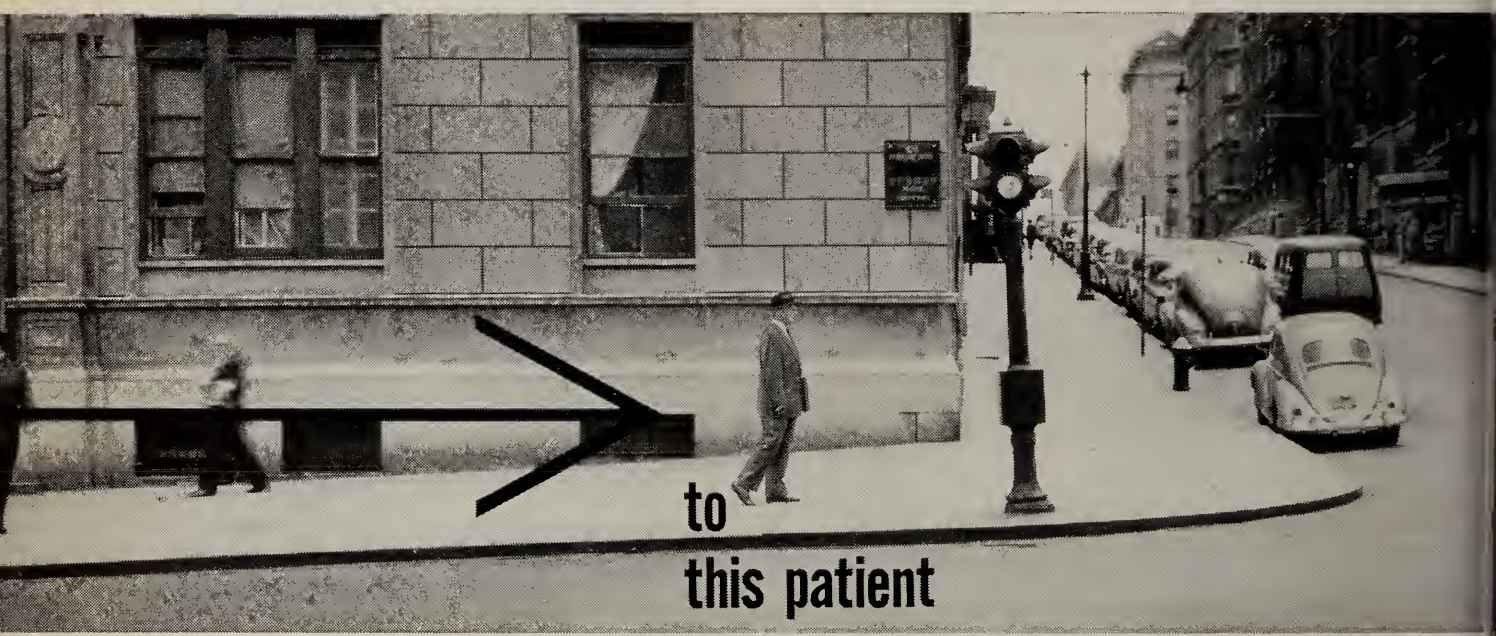
* * *

A well-known St. Paul heart specialist, **Dr. A. E. Venables,** has opened practice in Biwabik, Minnesota. Doctor Venables will serve as a general practitioner on at least a three-day schedule. Dr. Venables, who had retired, was prevailed upon to open an office by the Biwabik Chamber of Commerce.

* * *

Nopeming physician, **Dr. Reno W. Backus,** has been named to serve on Minnesota Tuberculosis and Health Association Committees. He will be on the Medical Advisory and Nominating Committees. Doctor Backus is medical director of the Nopeming Sanatorium. He will help to determine how and where to spend the association's funds in an all-out program to eliminate tuberculosis which requires the financing of year-around testing surveys to detect tuberculosis, education projects and work in the fields of research and rehabilitation. **Dr. Arthur M. Olsen,** Mayo Clinic, is chairman of the Medical Advisory Committee, **Dr. Viktor O. Wilson,** Rochester, is chairman of the program committee.

* * *



Dr. John Zachman, formerly of St. Paul, has become associated in the practice of medicine with his father, **Dr. A. H. Zachman** in Melrose. Doctor Zachman graduated from the University of Minnesota Medical School and was police surgeon for the city of St. Paul.

* * *

Drs. B. C. Ford, K. A. Peterson and **J. E. Eckdale,** of the Plaza Medical office in Marshall, announce the association of **Dr. Robert Phelps** in the practice of medicine. Doctor Phelps is a graduate of the Nebraska Medical College in Omaha.

* * *

The Medical Director of the Mineral Springs Sanatorium in Cannon Falls has been named to the qualifications and contract committee of the Minnesota Tuber-

culosis and Health Association. He is **Dr. Jesse E. Douglass,** who recently completed an intensive TB case-finding survey in the schools of Dakota, Goodhue and Rice counties.

* * *

Dr. Donald Amatuzio was recently honored for chemical and physiological investigations at the Jay Phillips research laboratory of Mount Sinai Hospital. Doctor Amatuzio is a specialist in research on the effects of dietary oils on the level of cholesterol in blood. He is a graduate of the University of Minnesota Medical School.

* * *

The government of Belgium has honored **Dr. C. Walton Lillehei** for his work with Belgian citizens who entered University Hospitals for heart surgery. He was awarded the decoration of the Order of Leopold.

* * *

Dr. E. Graham Howard, Spring Valley, has re-opened his office. Doctor Howard had been away but returned recently.

Dr. Charles Scheifley, Consultant in Medicine in the Mayo Clinic since 1946, has resigned his position from the permanent staff to continue his medical practice and research studies at another location. He also participated at the recent Sixth International Congress of Internal Medicine in Basel, Switzerland. Dr. Scheifley is the recipient of a traveling fellowship grant awarded jointly by the Sandoz Chemical Works, Inc., of Hanover, N. J., and Columbia University, New York City, on the basis of previous researches in international medicine conducted by Dr. Scheifley at the Mayo Clinic.

* * *

The Southern Chapter of the American Academy of General Practice held a regional seminar recently. Among those attending were **Drs. Donald Limbeck** and **Dale Bergeron** of LeSueur.

* * *

Dr. J. J. Ahlfs, Caledonia, has announced the appointment of **Dr. A. D. Davidson** in the practice of medicine. Dr. Davidson is a graduate of the University of Minnesota.

arlidin®

brand of nylidrin hydrochloride N.N.D.

safely increases local blood supply and oxygen where needed most... in distressed "walking" muscles for sustained, gratifying relief of pain and spasm in

intermittent claudication of
arteriosclerosis obliterans
thromboangiitis obliterans
diabetic atheromatosis

night leg cramps
ischemic ulcers
Raynaud's syndrome
cold feet, legs and hands

Arlidin is available in 6 mg. scored tablets, and 5 mg. per cc. parenteral solution. See PDR for dosage and packaging.

YOU CAN
COUNT ON
TAO®*
(triacetyloleandomycin)
even
in many
resistant
Staph*

1,928 published cases in the two years since TAO was released for general use show:

94.3% effectiveness in respiratory infections (617 cases including tonsillitis, staphylococcal and streptococcal pharyngitis, bronchitis, infectious asthma, broncho-pneumonia, lobar pneumonia, bronchiectasis, lung abscess, otitis.) **You can count on TAO.**

92% effectiveness in skin and soft tissue infections (900 cases including pyoderma, impetigo, acne, infected skin disorders, wounds, incisions and burns, furunculosis, abscess, cellulitis, chronic ulcer, adenitis.) **You can count on TAO.**

87.1% effectiveness in genitourinary infections (349 cases including urethritis, cystitis, pyelitis, pyelonephritis, orchitis, pelvic inflammation, acute gonococcal urethritis, lymphogranuloma venereum.) **You can count on TAO.**

75.8% effectiveness in diverse infections (62 cases including fever of undetermined origin, peritoneal abscess, osteitis, periarthritis, septic arthritis, staphylococcal enterocolitis, gastroenteritis, carriers of staphylococci.) **You can count on TAO.**

95.6% of 1,928 cases free of side effects—in the remaining 4.4%, reactions were chiefly mild gastrointestinal disturbances which seldom necessitated discontinuance of therapy.

*In 884 of 1,928 cases the causative organisms were mostly staphylococci. The majority of clinical isolates were found to be resistant to at least one of the commonly used antibiotics and many patients had failed to respond to previous therapy with one or more antibiotics. **TAO proved 93.4% effective in these 884 cases.**

Complete bibliography available on request.

DOSAGE: varies according to severity of infection. Usual adult dose—250 to 500 mg. q.i.d. Usual pediatric dose: 3-5 mg./lb. body weight every 6 hours.

NOTE: In some children, when TAO was administered at considerably higher than therapeutic levels for extended periods, transient-jaundice and other indications of liver dysfunction have been noted. A rapid and complete return to normal occurred when TAO was withdrawn.

SUPPLY: TAO CAPSULES—250 mg. and 125 mg., bottles of 60. TAO ORAL SUSPENSION—125 mg. per 5 cc. when reconstituted, palatable cherry flavor, 60 cc. bottles. TAO PEDIATRIC DROPS—100 mg. per cc. when reconstituted, flavorful; special calibrated dropper, 10 cc. bottles. INTRAMUSCULAR or INTRAVENOUS—10 cc. vials, as oleandomycin phosphate.

OTHER TAO FORMULATIONS ALSO AVAILABLE: TAO®-AC (Tao, analgesic, antihistaminic compound) capsules, bottles of 36. TAOMID® (Tao with Triple Sulfas)—tablets, bottles of 60. Oral Suspension—60 cc. bottles.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

Readers and Reviewers

The right is reserved to reject material submitted for reading or advertising columns. The views expressed in this journal do not necessarily represent those of the Minnesota State Medical Association or any of its constituents.

Advertisers and Subscribers

Classified advertising—15 cents a word; minimum charge $3.00; key number, 25c additional. Remittance should accompany order. Display advertising rates on request.

Annual Subscription—$5.00. Single copies—$0.50. Foreign and Canadian—$5.50.

Communications concerning advertising and subscriptions should be addressed to Minnesota Medicine, 496 Lowry Medical Arts Building, Saint Paul 2, Minnesota. Telephone CApital 4-5738.

Viruses and the Public's Health

ROBERT J. ANDERSON, M.D., M.P.H.
Assistant Surgeon General
United States Public Health Service
Chief, Communicable Disease Center
Atlanta, Georgia

VIRUSES are the most notorious cause of communicable disease today. They account for the lion's share of current infectious illness, ranging from the commonplace and mild to the rare, crippling, and deadly. The viral diseases of childhood—measles, mumps, chickenpox, and rubella—are accepted as a part of growing up and are considered alarming chiefly when they occur outside the usual age limits or when they pave the way for serious complications and chronic conditions. But others, particularly those that attack the central nervous system, like rabies, encephalitis, and poliomyelitis, spring to mind automatically whenever the term "dread diseases" is mentioned.

Few, if any, parts of the body seem to be safe from these highly selective, intracellular parasites. Some attack the brain and central nervous system, others the respiratory tract, still others the digestive tract, and so on down the line. There are even species that produce plantar warts on the soles of our feet. All living things, man, animals, and plants, are confronted with an array of viruses that have a unique preference for them as hosts and for specific systems within them. Even bacteria can be destroyed by tadpole-shaped viruses, called bacteriophages.

25th Annual John W. Bell Tuberculosis Lecture, delivered at a meeting of the Hennepin County Medical Society, Minneapolis, Minnesota, May 2, 1960.

Viruses, by their very nature, have presented obstacles to study. The majority of them have been unknown, unseen adversaries, manifesting themselves chiefly by what they do and how they spread. Consequently, they have been poorly understood. The contrast between our basic knowledge of viruses and bacteria shows up conspicuously in the degree of control that has been achieved against the two. Through accurate diagnosis, general and specific preventive activities, and chemotherapy, the sting has been removed from many bacterial diseases. Of course, there is still uncharted territory to be explored, interpreted, and conquered in this category also. Those of you who work in the tuberculosis field or with other bacterial diseases are aware of the unfinished business that stands between you and the goals you are seeking to achieve. Nevertheless, taken as a whole, the bacteria represent a diminishing threat to human life.

The situation is quite different with regard to the viral diseases. Spectacular triumphs against a few individual viral diseases stand out in a strong relief to the general rule. For instance, we have enough information on some to control them through immunization of human and animal hosts, or through control of insect vectors and environmental factors. Oddly enough, the first types of immunization ever to be developed were directed against viral diseases—innoculation and vaccination for smallpox and prophylactic treatment for rabies. For most viral diseases, however, the fund of knowledge is still inadequate to the task. At present, only a few are preventable and even fewer are amenable to chemotherapy—principally those of the psittacosis-lymphogranuloma group.

Elaboration of control measures for any infectious disease usually awaits precise knowledge of the causative organism, its ecology, and modes of spread. We are just beginning to strip the viruses of the obscurity that has sheltered them in the past. Under the spotlight of increasing intelligence, earlier concepts of viral diseases are enlarging and sometimes changing and the number of known pathogenic viruses is skyrocketing. At the turn of the century, only a dozen or so human viruses were known. Fifteen years ago, there were probably not more than 70. Today there are upwards of 150, with new ones coming up regularly. At last, we are beginning to hurdle series of obstacles that stood in the way of understanding these elusive pathogens. In this lies the expectation that we will soon accumulate sufficient knowledge to tip the balance against an increasing number of viral diseases.

The word "virus" originated during the Middle Ages to denote a venomous exudate from wounds. Later, invisible substances were found to be the cause rather than the result of infective processes. With acceptance of the germ theory of disease, bacteria were isolated, cultured, examined under the microscope, identified and associated with specific disease conditions. Their ecology was studied, their modes of spread were determined, and rational methods of control were developed. However, there remained a number of infectious diseases for which no bacteria could be found. Bacteriologists found that infective particles, small enough to pass through the pores of porcelain filters, could produce disease. The term "filterable" virus was applied to these pathogenic substances for many years. Because the tools of the bacteriologist, chemist, and physicist were inadequate to penetrate their secrets, viruses remained invisible and inscrutable. They were distinguishable by their capacity to spread and produce disease.

Viruses have many qualities that set them apart from bacteria. Most of them are too small to be examined under the ordinary microscope and identified by their morphological characteristics. They cannot be grown in culture media suitable for bacteria, since they multiply and take on the attributes of life only within susceptible living cells. They cannot be tasted, smelled, touched, or measured by methods commonly used for other pathogens. Like ideas, they are intangible, pervasive, able to spread and bear fruit only among those who are susceptible to them. To carry the comparison a step farther, they are equally difficult to defeat. That is why we speak of the "virus" of ideologies, political and social, that are in opposition to our way of life.

The first real breakthrough in the scientific study of viruses came years ago with the discovery that some human and animal disease processes could be reproduced in the suckling white mouse and that virus could be cultivated and harvested in the embryonated chicken egg. The mouse has been joined by more expensive and complicated animals such as the Rhesus monkey. However, we are still handicapped for convenient intact laboratory animals to serve as substitute hosts for

most of the human viral diseases.

Until recently, cultivation and isolation of viruses was a cumbersome, tedious, and expensive procedure. Advances in tissue culture methods have now placed it on a more practical footing. The use of tissue cultures for the propagation of viruses dates back to 1913. Inherent problems limited their use to the research laboratory. In 1949, Enders and his associates reported growing poliovirus in monkey kidney cells, the first successful attempt to cultivate it in non-nervous system tissues. Since then several kinds of tissue cells have proved suitable for the propagation of one virus or another. Monkey kidney cells, human amnion cells, HeLa cells, and others are now widely used for the growth and differentiation of viruses. The ordinary microscope and antibiotics have found their niche in virology. The destructive changes that occur in infected tissues can be seen and studied under the low-power microscope. Antibiotics, which are of no avail in the treatment of most viral diseases, serve as an adjunct to virus studies by keeping down bacterial contamination in the tissue cultures.

Serological work on the viruses has also advanced, with laboratory techniques developing around specific antigen-antibody systems. Most of these tests are not yet specific enough for clinical epidemiological purposes. They provide evidence of past infection, which is useful in constructing a profile of previous viral experience within a community. So far, it has not been possible to distinguish between the antibodies acquired by natural infection for poliovirus, for example, from those induced by vaccine.

Some interesting questions have been raised as a result of finding rabies antibodies in healthy, trapped wild animals. Bats have been known to carry the virus for months without developing clinical symptoms of the disease, but they were thought to be exceptional in this respect. How and when these other animals received their exposure to the virus is unknown. Since we have no knowledge of subclinical rabies infections, the significance of the finding is not understood at this time.

A number of serological tests for viruses are being studied in conjunction with the fluorescent antibody technique for rapid diagnosis. The diagnostic test for rabies has been field tested and found specific and practical enough for wide-scale use, with results obtainable within a day. To the bite victim and the physician or public health worker who must cast the die for or against the Pasteur treatment, this time-saving element is of inestimable value.

The electron microscope, with magnifications up to 200,000 times, has brought viruses within the range of vision. A technique called metal shadow casting provides the necessary contrast between the background material and the viral particles. Many investigators have photographed different viruses of varying sizes and shapes. Each follows its own geometric pattern—the influenza virus, for example, looks like a fluffy powder puff. The antibody molecule, which immunochemists believe is a few millimicrons smaller than the encephalitis virus may someday be seen.

Scores of previously undiscovered viruses have been identified within the past few years. When so many new microorganisms come to light so rapidly, it takes time to sort the pathogens from the harmless saprophytes and to determine whether they are agents of known or new diseases. A virus is usually considered pathogenic when it is frequently found during a characteristic illness; when specific antibodies develop in the host; and when the isolated virus produces a similar disease picture in other susceptible hosts.

As the new viruses have been identified and associated with disease states, many have been found to produce signs and symptoms that formerly pointed to other agents. This characteristic is shared with other kinds of pathogens also. In suspected tuberculosis, the culprit may turn out to be a fungus, one of many atypical acid-fast bacilli, or something else quite distinct from the tubercle bacilli. Wisdom dictates that a clinical diagnosis of poliomyelitis be followed by a question mark until the presence of poliovirus is confirmed in the laboratory, for the symptoms may be caused by one of the other enteroviruses. The encephalitis syndrome requires careful definition of its source; it may be produced by any of a variety of viruses, arthropod-borne and otherwise, bacteria, fungi, or protozoa, or chemicals. For reasons such as these, diagnostic dependence on clinical evidence alone has lost much of its validity in regard to the infectious diseases. In the closely-welded partnership now necessary between the clinician and the laboratory diagnostician, the laboratory acts as arbiter when the identity of a causative agent is in doubt.

But the diagnostic dilemma is not necessarily

solved when a disease state is correctly tagged with the family name of the causative organism. Also to be taken into consideration are the types and strains, which often have individual antigenic properties. This is true of other organisms as well. Only certain strains of the staphylococcus, for example, are antibiotic resistant and produce epidemics.

The classification and naming of viruses is still in a fundamental stage. The Coxsackie viruses were so named because they were first isolated from residents of Coxsackie, New York. Together with the polio and ECHO viruses, they are classified as enteroviruses because their habitat is in the intestinal tract. Their most drastic effect is on the central nervous system. Members of the ECHO group were originally described as orphans in search of a disease. The word "ECHO" was coined from the first letter of each attribute of these viruses: enteric, cytopathic, human, and orphan—in the sense that they had no known link with any pathological condition at the time they were discovered. The arthropod-borne viruses do not have one single property in common. Many that are transmitted by mosquitoes and ticks produce dissimilar diseases like encephalitis. yellow fever, dengue, and a host of others. Some have been placed in the group solely because they have an antigenic relationship with known members. Like the bat salivary gland virus, they may not be spread by arthropods at all. Dissatisfaction with nomenclature dates back to antiquity. More than 2,000 years ago, Plato commented in *The Republic:* "They do certainly give very strange and newfangled names to diseases."

Despite the number of known viruses today and the unfolding of their pathogenic role, the etiology of the vast majority of infections of the respiratory, gastrointestinal, and central nervous systems is still undetermined. The present status of virology has been compared to that attained in bacteriology fifty years ago.

Probably no infectious diseases are more persistent and widespread than those of the respiratory tract. The bacterial diseases have been studied extensively and a great deal of progress has been made against them. Advanced chemotherapy has pulled down the mortality from these diseases, although the morbidity rate still leaves much to meted from first place as a death-dealing infectious be desired. Tuberculosis, for example, has plum-disease to twelfth place, but the attack rate has not dropped as drastically. Bacterial pneumonias also claim far fewer lives than they once did. The viral respiratory diseases are now of major concern. Until recently, a sound etiological relationship of viruses to major human respiratory diseases had been established only for influenza and psittacosis. Both of these viruses were identified during the 1930's, and both have been the subject of extensive investigation.

Influenza pandemics and epidemics have long been of concern to people who are interested in respiratory diseases. Even when the influenza itself is not particularly severe, it is followed by a wave of mortality in excess of normal expectations. These deaths are usually attributed to pulmonary and cardiac conditions. It is well known that pathogenic bacteria take advantage of the derangement of the respiratory tract during an influenza attack and readily produce pneumonia. Of the many possible complications in influenza. only the bacterial yield to chemotherapy.

Since the influenza virus was isolated in 1933, four major immunological types—A, B, C, and D —have been differentiated. Most epidemics have been associated with Type A, and some outbreaks with Type B. Type C appears to be relatively rare. Type D is variously known as parainfluenza 3 or Sendai virus. We will refer to it later. Each of these influenza virus types has a multitude of strains, which occur in families in Types A and B. These strains are so closely related within their respective families that immunity to one confers immunity to others in the same family but does not extend to other families of the same type. The Asian strain that swept across the world in 1957 was a new family of Type A virus with antigenic properties different from those of other strains. Neutralizing antibodies were found only in a few elderly people in the Netherlands and the Boston, Mass., area. Possibly the Asian strain was somehow related to the one responsible for the 1890 influenza epidemic. Because the Asian strain was different from those that have been prevalent within the lifetime of most people. susceptibility was high. Also, existing vaccines were ineffective against it and a special one had to be developed using the Asian antigen.

We are all familiar with the story of how the Asian strain was isolated and how its spread was traced from Hong Kong around the world. Excellent health teamwork, nationally and internationally, played a large part in helping us

prepare for the epidemic in this country. Time and place also worked to our advantage. Summer intervened between the alert signal and the establishment of the virus in this country. During the relatively influenza-free summer months, approximately 40 million doses of vaccine were started in production. Had the mutant strain developed in this hemisphere north of the Equator, we would not have had this period of grace.

Influenza viruses of one type or another are almost constantly present in a few people everywhere, and the general population develops some degree of immunity against them. When variants develop, as they frequently do with influenza viruses, the new strains that are least readily neutralized by existing antibodies in the population have the best chance to survive and establish themselves as successful pathogens. Specific vaccines will probably always have to be developed against such strains under emergency conditions. Vaccination is our only weapon against epidemic influenza.

Although Asian influenza was not caused by a lethal strain, the familiar pattern of excess pneumonia-influenza mortality followed its successive waves, particularly among elderly people. In the six-month period from October 1957 through March 1958, there were nearly 88,000 excess deaths in this country as compared with comparable periods in 1956 and 1957.

A profusion of myxoviruses, ECHO viruses, adenoviruses, and others have been identified and associated with respiratory infections in recent years.

When the myxoviruses were first identified, the group included only the viruses for influenza, mumps, and Newcastle disease of fowls. A number of new viruses have since been added to the group. Influenza virus D, better known as Sendai virus and as parainfluenza 3, was isolated in Japan, where it was reported to be an important cause of pneumonitis in infants. It was also recovered from rodents and swine. In this country, this virus caused 50 per cent more cases of acute respiratory disease and pneumonia in hospitalized children in one city during the Asian influenza epidemic than the Asian strain itself. It has now been isolated from nasal secretions and diseased lungs in calves and cattle during outbreaks of respiratory disease among them. This virus is being studied by the Public Health Service and the University of Maryland as a possible cause of shipping fever in livestock. Parainfluenza virus 3 spreads so readily from one person to another that no animal source is needed to explain frequent human infections. However, the animal study may provide a better understanding of viral respiratory disease in humans as well as in cattle and also give some indication of the value of vaccines against it.

When the adenoviruses were found in association with acute respiratory illness in military populations in 1954, it was hoped that the etiology of much undiagnosed illness would be established. Although these agents have been isolated from human tonsils and adenoids all over the world, they account for only a small proportion of the total respiratory illness in civilian populations. During the first flush of hope about these viruses, a vaccine was developed against them. It is now used chiefly in military populations where the incidence of adenovirus infections remains high, particularly among recruits.

Some of the ECHO 10 viruses in the enterovirus group are thought to cause respiratory infections in children. Sabin has proposed reclassifying ECHO 10 as Type 1 of the new Reovirus group because of its size, effect on cells, epidemiological pattern, and its association with respiratory diseases in man and lower animals.

In quest of the cause of the common cold, investigators have recovered a number of miscellaneous viruses, but none has proved to be the single cause. The Salisbury Hospital's Common Cold Research Unit in England has persistently attempted to establish the relationship of a variety of viral isolates with common cold symptoms in human volunteers. They introduce the isolates directly into the nasal passages of the volunteers. It appears the humidity and a number of unknown factors influence the host response to infection.

Another group, the enteroviruses, is composed of at least sixty distinct strains of poliomyelitis, Coxsackie, and ECHO viruses. They have much in common in regard to laboratory characteristics, particle size, disease syndromes, and epidemiologic pattern. These viruses are important public health problems because they cause widespread epidemics, particularly during the summer. Man appears to be the natural host for these viruses, although some ECHO types have been recovered from monkeys, cattle, and swine. Transmission of the enteroviruses follows a fairly direct route from person to person.

The three types of polioviruses are the best known of this classification. They have been studied over decades and an over-all picture has been obtained of the pattern of their occurrence, routes of transmission, and results of their presence. The polioviruses are the only members of the category for which we have some measure of control. The Salk vaccine has proved highly effective in preventing paralytic cases of polio and has maintained its safety since the initial incident in 1955. Despite the availability of a safe, effective vaccine, the annual case rate of poliomyelitis has continued to rise in the past several years. Analysis of morbidity data shows the heaviest concentration of paralytic cases among unvaccinated preschool children in low socio-economic groups. Experience has not confirmed the belief that people universally and voluntarily would avail themselves of the protection afforded by the vaccine. Some 34,000,000 people in the vulnerable under-forty-years-of-age group, including half of the children under five, have not had a single dose of the vaccine.

Debates have raged around the comparative advantages of a killed virus vaccine and one made from attenuated strains that have lost their power to attack the nervous system. Proponents of the killed vaccine point to its safety. It is recognized, however, that an immunized individual can still pick up, propagate, and excrete the virulent strains. Although he himself is immune, he constitutes a hazard to his susceptible associates. Proponents of the live vaccine point to the possible extension of protection beyond the primary recipients of the vaccine. They state that secondhand immunizations occur as attenuated strains pass naturally from vaccinated individuals to their contacts. These naturally infected persons would then become links in the further transmission of the strains. Succeeding generations of the tamed and disciplined strains would possibly supplant the wild virulent strains in the population. The successful application of this theory depends on the continued stability of the attenuated strains through innumerable human passages. To operate as predicted, the strains would not only have to retain their capacity to induce antibodies against their virulent counterparts, but also show no sign of reverting to their neurotropic characteristics.

Attenuated vaccines have already been tested with no ill effects in Nicaragua and Russia, and are now being tried under carefully controlled conditions in other parts of the world including your own state of Minnesota. In a recently completed study in a suburb of Philadelphia, live attenuated poliovirus was administered orally to eighteen infants. Antibody production was good, with seventeen of the children responding to all three types of virus and the eighteenth to types 1 and 3 only. Within fifteen weeks, 42 per cent of the siblings and 11 per cent of the susceptible adults had acquired antibodies. Live virus was then fed to the sero-negative adults and siblings under fourteen years of age with 50 per cent and 91 per cent respectively developing infection. Attempts to reinfect the individuals who had been fed virus or who had acquired a natural infection showed that they had developed resistance to it, for they excreted virus for only two days. There were no illnesses related to the vaccine. After one to three human passages, recovered virus was inoculated intracerebrally in monkeys with no significant evidence of neuropathogenicity.

Another study at Tulane University School of Medicine is underway to determine the susceptibility of newborn infants to the Sabin live poliovirus. At two and thirty days of age, infants will be fed various doses of all three types of attenuated virus, separately and in combination. Blood and fecal specimens will be studied for the presence of antibodies and for the excretion of virus respectively.

These examples indicate the painstaking and detailed investigations that must be undertaken before a vaccine can be released for general use.

The Coxsackie and ECHO viruses are more versatile than the polioviruses. Their repertoire includes non-specific febrile illness, with or without rash, aseptic meningitis, herpangina, pleurodynia, myocarditis, and sometimes respiratory and diarrheal diseases, depending on the species and strains involved. Clinical features of enterovirus infections frequently overlap. For this reason, laboratory diagnosis is essential in the specific diagnosis of enterovirus disease. State and regional virus laboratories across the country have access to the Communicable Disease Center's reference diagnosis service when the identity of an isolate is in doubt.

The Coxsackie viruses, discovered in 1948 during poliomyelitis investigations, were found initially in association with non-paralytic polio, mainly in young people. A few years later, they were joined by the ECHO viruses.

As producers of aseptic meningitis, the Coxsackie and ECHO viruses act very much like the polioviruses. Paralysis, especially residual paralysis, is rare. Approximately, a score of paralytic cases have been reported in the literature during the past ten years. Development of paralysis is generally presumed to indicate poliomyelitis; absence of the syndrome does not necessarily absolve the polio agents.

The Coxsackie and ECHO viruses are believed to be worldwide, and like poliovirus, more endemic in warmer climates. Infection is year-round, with more illness during warm months. They follow the poliovirus pattern in regard to age, sex, race, and socio-economic groups.

Epidemics are typically localized and sporadic, varying in etiology from place to place during the same year. Iowa has studied the enteroviruses extensively, having had an unusual experience with them. Within a radius of 100 miles, an epidemic of ECHO 4 occurred in 1955, of Coxsackie B5 in 1956, and of poliovirus 1 in 1959.

Every possible combination of enteroviral infection has been found. This has led to a great deal of speculation regarding interference, non-interference, and potentiation between virus types. So far, there is little direct information. Sabin and others have encountered instances where naturally occurring enteroviruses appeared to interfere with live virus polio vaccine. Some authors have reported that polio epidemics started later than usual when they were preceded in the area by other enteroviral epidemics.

The enteroviruses are intimately associated with man in the absence of disease, and actual illness appears to be an unusual response. Perhaps this should not be considered strange, since nature furnishes a number of instances in which humans, other animals, plants, insects, and even bacteria harbor viruses, yet manage to keep the host-parasite relationship in a state of equilibrium.

Because the enteroviruses constitute an important public health problem, the Communicable Disease Center is initiating a surveillance program on them in ten to twelve cities throughout the country. Minneapolis will be included as one of the cities selected for the large-scale live polio vaccine field study. Monthly fecal specimens and annual blood specimens will be obtained from healthy young children for analysis of seasonal, annual, and geographic variation of polio, Coxsackie, and ECHO viruses. By comparing the subclinical flow of enterovirus infections with the occurrence of clinical disease, some clue may emerge to explain, and possibly predict, outbreaks.

Also, the study will provide a means of accumulating a background picture of the prevalence and characteristics of naturally-occurring wild polioviruses and other enteroviruses before the live virus polio vaccine is used. It should then be possible to determine the effect of its use on the natural occurrence of these viruses.

Many of the viruses, old and new, are specific for one kind of animal or another. The arthropod-borne viruses are particularly interesting because at least three types of creatures have a part in the infection cycle. The first viral disease in which arthropods were shown to be essential in the maintenance and dissemination was yellow fever. Later their role was defined in regard to dengue and several encephalitis viruses. Upwards of 100 viral agents are now known to be transmitted by arthropods, particularly mosquitoes and ticks. In this country, the most important arbor viruses, as they are called for brevity, are eastern, western, and St. Louis encephalitis viruses. Each of these is recognized as a public health problem somewhere in the United States. Birds and mosquitoes apparently maintain eastern encephalitis in fresh water swamps in the eastern part of the country; hibernating mosquitoes are thought to be important in keeping western encephalitis alive through adverse weather in the western part of the country, and birds may carry latent St. Louis virus. It appears that man is an incidental and terminal host in these infections.

One highly specialized type of virus invades bacterial cells and literally disintegrates the host cell. These bacteriophages have been put to use by the laboratory diagnostician and the epidemiologist. Antibiotic-resistant epidemic strains of staphylococcus can be identified by phage typing. Their spread can then be traced through the hospital or community. Phage-typing is of no significance in scattered infections; it is an invaluable tool in an epidemic. A few years ago, the technique helped track down the source responsible for thirty-four cases of typhoid fever in eight states. The common denominator in this outbreak was a summer meeting of a religious sect in the Midwest.

The capacity of bacteriophages to destroy the bacteria susceptible to them has led to some conjecture in regard to their potential therapeutic

value. So far, however, nothing positive has come out of limited experimental work in this direction.

Judging from the sheer number of viruses brought to light in recent years, and the number of remaining diseases for which we have no known cause, may we not expect a growing harvest of new viruses and a linking between them and these diseases? Even now, the relationship between viruses, tumors, and other diseases of unknown etiology is being probed. Also under scrutiny is the disease-producing effect of viruses and bacteria in combination. The serious import of bacterial complications superimposed on viral infections, such as influenza, is a case in point.

As we move into a new way of life characterized by urbanization, industrial expansion, and technological developments, we need to explore their relationship with viral infections. The physical and chemical contamination of our food, water, and air may have more bearing on the subject than appears at first glance.

For example, abundance evidence exists that viral hepatitis is water borne. Many communities are pouring enormous quantities of disease-carrying sewage—raw and untreated—into the water sources of their downstream neighbors. As you know, water treatment is designed to cope with enteric bacteria, not with viruses. In addition to human and domestic wastes, some 7,000 new industrial and agricultural chemicals also are finding their way into our water supply each year. If, as some scientists surmise, detergents dumped into our water increase cell permeability, these chemicals alone may be heightening our susceptibility to hepatitis and other viral infections. What the cumulative effect of all the contaminants may be is unknown.

Air—the environmental factor that surrounds us twenty-four hours a day and without which we cannot exist—has become the carrier of a large amount of pollutants in urban areas everywhere. The cleanest air in these communities is five times as dirty as that in non-urban areas, according to the National Conference on Air Pollution, held in Washington, D. C., in 1958. Automobiles, barbecue pits, trash burners, furnaces, and domestic and industrial smoke stacks belch harmful gases and unconsumed chemical particles into the air. The National Air Sampling Network monitors the air in 240 cities and non-urban sites, analyzing samples for thirty specific inorganic substances. Some of these substances are being tested for possible tumor production in experimental animal colonies. Follow-up studies of residents of Donora, Pennsylvania, and other smog-stricken cities show that contaminated air apparently plays a role in the development of chronic diseases—respiratory and chest conditions, among others. It seems quite likely that contaminants in the air pave the way for viral respiratory infections.

The use of antibiotics in animal feeds raises questions, also. If sufficient amounts are carried over into our table meats and poultry, they may decrease the normal complement of intestinal bacteria, leaving the field free of competition for the viruses.

These are only a few of the possible ways in which modern life can contribute to our susceptibility to viruses. Hovering over the entire subject, of course, is the question of host response. We still do not know what makes one person sicken and another remain well under the onslaught of pathogenic organisms. We are still speculating about the long-term effect of the stresses inherent in our way of life.

Virology may be on the threshold of its golden age, just as bacteriology was many years ago. Research is constantly broadening the horizon. While research is seeking answers to basic questions, there is much we can do on the basis of the knowledge we already have. Like the poet, we can try to see the unseen in the seen. This is not an unrealistic approach, for the effects of viruses can be seen and studied, although the agents themselves are not readily visible. Pioneers in tuberculosis work tackled control programs while knowledge of the organism was in its infancy. Laboratory research is still going on all over the world to fill the voids in our knowledge. In the viral disease field, epidemiologists and physicians are helping to trace the pattern of viral spread and behavior, whether the agents are known or unknown, single or multiple. They have ample precedent for bringing their own resourcefulness to bear on the problem of control.

The idea of viruses is intriguing. It is full of subleties and imponderables that beckon us on. Best of all, it plants within us the virus of ideas that will take shape and grow. Where they will lead, we cannot predict. Bacteriology gave medical science the investigative approach. Virology, as it matures, may open new medical frontiers that now seem dim and far away.

ILLNESSES DUE TO COXSACKIE VIRUSES

1. HERPANGINA
2. "THREE DAY FEVER"
3. ASEPTIC MENINGITIS
4. EPIDEMIC PLEURODYNIA
5. PERICARDITIS
6. MYOCARDITIS (INFANT AND ADULT TYPES)
7. ORCHITIS
8. LYMPHADENOPATHY AND SPLENOMEGALY SYNDROME
9. COMBINATIONS OF THE ABOVE.

Coxsackie Disease

Report of a Syndrome due to Coxsackie Virus Group B, Type 2

WILLIAM R. FIFER, M.D.
Minneapolis, Minnesota

Since it was first discovered in 1947, Coxsackie virus has been shown to cause a variety of syndromes. These are discussed in detail and illustrated by a case report.

THE PURPOSE of this paper is to describe a clinical syndrome consisting of pleurodynia, pericarditis and orchitis caused by Coxsackie virus, Type B-2.

Coxsackie virus was discovered in 1947. Group B Coxsackie virus was shown to cause epidemic pleurodynia (epidemic myalgia, Bornholm disease) and a form of aseptic meningitis in 1950. Group A Coxsackie virus was shown to cause herpangina in 1951, and in 1952 a Group B virus was shown to be causally related to epidemic myocarditis in the newborn.[1]

[1]Presented at the spring meeting of the Minnesota Society for Internal Medicine, Saint Paul, Minnesota, in May, 1960.

Virology

Classification of Coxsackie viruses into Groups A and B is based on the type of lesions produced by these agents in suckling mice. Group A virus produces an intense myositis which causes muscle paralysis in injected mice, and certain strains of Group A produce poliomyelitis-like lesions. Group B virus produces degeneration of fat, encephalomalacia, hepatitis, myocarditis and occasionally pancreatitis in injected mice. This tropism is relatively specific but is in part dependent upon the route of inoculation.

Five distinct types of Group B and 25 types of Group A have been separated antigenically.[2] All five types of Group B and many of the Group A types are known to cause human disease.

Clinical Illnesses Due to Coxsackie Viruses

The many syndromes ascribed to Coxsackie viruses are listed in Table I.[3] Group B Coxsackie

viruses cause more different syndromes than Group A, as shown in Table II.

Herpangina is a summer disease of children due to Group A Coxsackie viruses. It is recognizable by the distinctive ulcerative lesions in the pharynx, and is usually a benign and uncomplicated illness.

Aseptic meningitis has been shown to be caused by all five types of Group B Coxsackie virus by isolation of the virus from spinal fluid of patients ill with this disease. Many such cases are clinically assumed to be instances of non-paralytic poliomyelitis. One such epidemic in Minnesota in 1956 was due to Coxsackie B-5 virus.[4] Aseptic meningitis may also co-exist with pleurodynia,[5] and may be caused by certain Group A viruses.

Epidemic pleurodynia (Bornholm disease) has been described clinically since 1872. For ten years various epidemics have been proved to be caused by various types of Group B Coxsackie virus, but Group A has not been found to cause this illness. Orchitis is the most common complication of pleurodynia, and patients with orchitis of unknown cause should be studied for Coxsackie infection.[5]

Myocarditis of the newborn has been shown to be produced by Group B Coxsackie viruses since the 1952 epidemic of Bornholm disease in Johannesburg. Various types of the B Group have been recovered from feces and heart muscle in cases of myocarditis neonatorum. Myocarditis has also been described in other than newborn patients. McLean[6] described myocarditis in a five-year-old boy due to Coxsackie B-2 virus. Null and Castle[3] found two cases of myocarditis which produced frank congestive heart failure in adults in the Salt Lake City epidemic due to Coxsackie B-5 virus.

Benign pericarditis has been reported due to Coxsackie virus type B-4[7] and B-5[8] in 1957. Movitt[9] reported cases of pericarditis due to types B-3 and A-1 in 1958. This is the only case in the literature of pericarditis due to a Group A Coxsackie virus.

In 1958, McLean and co-authors[10] saw four children with pericarditis during an epidemic of pleurodynia and aseptic meningitis in southern Ontario which was proved to be due to Coxsackie B-5 virus. They recovered type B-5 virus from the feces of all of these children with pericarditis, and demonstrated a significant rise in antibody titer to this virus in the patients' sera.

In 1959, Roberts and co-workers[11] discussed Coxsackie pericarditis and reported a case of pleurodynia, aseptic meningitis, orchitis and pericarditis due to Coxsackie B-5. Sode reported a case of pericarditis and pneumonitis due to Coxsackie B-2 virus in 1959.[2] Bell and Meis[12] reported a laboratory infection with Coxsackie B-3 virus which produced pericarditis and pleurodynia.

Two epidemics have been reported which illustrate the spectrum of disease produced by Coxsackie virus. Null and Castle[3] described an epidemic in Salt Lake City due to Coxsackie B-5 virus in which seventeen cases were well studied. Eleven of these had pleurodynia, one had aseptic meningitis, one had meningoencephalitis with paralysis, and four had pericarditis. As mentioned, two of these four cases of pericarditis had an associated myocarditis of sufficient degree to cause frank congestive heart failure. Gordon et al[5] reported the extensive California epidemic of 1956 due to Coxsackie B-5 virus. These workers studied 500 cases of epidemic pleurodynia, mostly in children and young adults. They noted, in addition to "pure" syndromes of pleurodynia and aseptic meningitis, combinations of these two. They also found seven cases of pericarditis in this epidemic and noted pleural effusion in three cases. One of Movitt's cases also had a large bloody pleural effusion.[9]

Gillett[13] summarized the reported cases of pericarditis due to Coxsackie viruses in 1959, and listed a total of nineteen cases. Sixteen of these were due to type B-5, two were due to type B-3, and one was due to type A-1.

Diagnosis

It is obvious that one must think of Coxsackie virus infection whenever one sees a clinical syndrome of chest pain, pericarditis, orchitis, or aseptic meningitis. Combinations of these or epidemics of these illnesses should be strongly suggestive of the diagnosis of Coxsackie disease.

Herpangina must be differentiated from primary herpetic gingivostomatitis. Aseptic meningitis due to Coxsackie virus must be differentiated from mumps meningoencephalitis, lymphocytic choriomeningitis, and non-paralytic poliomyelitis. Pleurodynia may simulate pneumonia, pleurisy, or coronary thrombosis. The combination of meningoencephalitis and orchitis may suggest either mumps or a Coxsackie infection.

The diagnostic criteria for a Coxsackie virus infection are:[14]

1. A clinical syndrome of previously unknown

or questionable etiology which is not associated with any known pathogens.

2. Antibody response to Coxsackie virus of four-fold or greater in paired serum specimens.[15]

3. A Coxsackie virus should be recovered from the patient.

The following report presents a case in which these diagnostic criteria were met.

Case Report

A white male office worker, aged thirty-three, became ill September 16, 1959, with fever, interscapular and substernal chest pain. The pain was aggravated by respiration. He denied any symptoms of upper respiratory infection. On examination, the temperature was 101° F and the patient was "splinting" the chest in severe pain. The heart and lungs were normal at this time. No pericardial or pleural friction rub was heard. Chest radiograph and electrocardiogram revealed no abnormalities on this date.

On September 19, the patient was seen again and still complained of severe chest pain requiring potent analgesic agents. On this occasion, a loud pericardial friction rub was noted which disappeared within the subsequent twenty-four hours. He was admitted to the hospital for further study on September 20. He remained febrile and in pain on that day and the next, and on the latter day he had intermittent periods of confusion and disorientation. Repeated physical examinations were essentially normal. Repeat chest radiograph and electrocardiogram on September 20 gave normal findings.

Laboratory studies were as follows: hemoglobin 16.1 grams per cent, white blood count 7,800, (neurophils 52%, lymphocytes 41%, monocytes 2%, eosinophils 5%). Sedimentation rate 25 mm/hour. Throat culture grew only normal flora. Urinalysis was normal. ASO titer was 12 Todd units. VDRL negative. Heterophile agglutination positive 1:28. Cold agglutination negative. No rise in titer developed against mumps, Western-equine encephalitis, or lymphocytic choriomeningitis virus in paired serum specimens obtained on Septemer 21 and 30.

Coxsackie virus type B-2 was isolated from the stool on October 2. The neutralizing antibody titer against Coxsackie virus B-2 rose from less than 1:4 on September 22 to 1:256 on October 18.

The patient became afebrile on September 22 and was discharged from the hospital. He remained well until September 27 when he again developed fever, chest pain and an acute orchitis. At this time, examination disclosed a transient pleural friction rub and evidence of acute orchitis. Laboratory work on this date disclosed a white blood count of 11,350 with 81 per cent neutrophils, 18 per cent lymphocytes and 1 per cent basophils. Sedimentation rate was 29 mm. per hour. Repeat chest radiograph on September 28 was again normal except for elevation of the right diaphragm. By September 30, the orchitis subsided along with the chest pain and fever, and the patient made an uncomplicated and uneventful recovery.

Summary

A syndrome of pericarditis, pleurodynia, and orchitis has been presented which was proved to be due to Coxsackie virus type B-2 by isolation of this agent from the stool and by demonstration of an eight-fold increase in specific neutralizing antibodies.

The spectrum of disease caused by Coxsackie virus is broad. Herpangina is classically due to Group A viruses. Aseptic meningitis, pleurodynia and neonatal myocarditis are well recognized expressions of Group B infection.

Most recently, pericarditis has been reported due to various Group B types, and combinations of pleurodynia, pericarditis, myocarditis, meningitis and orchitis are now being recognized.

Diagnosis and Treatment of HISTOPLASMOSIS

J. LEWIS YATES, M.D.
Mt. Vernon, Missouri

HISTOPLASMOSIS is a systemic fungus infection which resembles tuberculosis in many important respects. The infection is acquired by the inhalation of spores dispersed in the air from point sources in soil, particularly if contaminated with chicken, turkey, pigeon and bat droppings. The mycelial phase of the fungus occurs on laboratory cultures and in the soil, and the yeast phase in the tissues.[1,6,8] The majority of people who acquire the infection develop an acute benign type of disease which frequently is asymptomatic but may simulate influenza. Some of these patients will show a miliary type of x-ray picture and occasionally are admitted to tuberculosis sanatoria as having so-called "miliary tuberculosis."

Dr. Yates is Chief of Medicine, Missouri State Sanatorium, Mt. Vernon, Missouri.

The incubation period of the acute benign disease varies from three days to three weeks, depending upon the intensity of exposure. Exposure during work such as cleaning or tearing down a chicken house may result in small epidemics in which several members of a family or group may develop different degrees of disease. The infection is not transmitted from man to man. Animals in the endemic areas also acquire the infection.[6,8,10]

In the endemic areas, the skin test is positive in a variable percentage of the general population. In Missouri, this includes approximately 80 per cent of the people. It has been estimated that approximately 30,000,000 people in the United States have been infected with *Histoplasma capsulatum*.[6,8] The vast majority of these persons have had the mild, so-called "primary" or acute benign disease, and seldom have symptomatology which requires medical care. Less than 1 per cent develop serious types of disease that will eventually require specific antifungal treatment. If only 0.5 per cent have serious types of the disease, this constitutes a significant medical problem. About 10 per cent of people being admitted to sanatoria in the highly endemic areas have clinically significant histoplasmosis.[9] There is a higher incidence of serious types of disease in men.

Complement-fixation tests and histoplasmin skin tests are useful screening procedures. The precipitin test is less sensitive than the complement-fixation but as applied with the gel-precipitin technique may be a more practical and rapid screening procedure.[1,2,3,5,8,10] As may be seen from Table I, 89 per cent of the culturally proved cases at the Missouri State Sanatorium have positive serology and 79 per cent, positive skin tests. If there is a complement-fixation titer of 1/8 or greater, careful cultural studies of sputum, bone marrow and blood should be performed. How long the complement-fixation titer remains elevated after an acute benign episode is not known. It is of interest to note (Table II) that only fourteen of forty-nine cases with histological proof of disease, but with negative cultures from sputum and resected tissue, have positive serology. This may be explained by considering the organisms demonstrated in such cases as dead or "ghosts." One-third of the patients with significant complement-fixation titers have been found to have active chronic pulmonary histoplasmosis. At least six sputum cultures are necessary for an adequate study.

The factors in the host-parasite relationship which lead to the development of serious types of disease are incompletely understood. Host nutrition undoubtedly plays a role, as well as age, and infecting dose. There are different strains of *Histoplasma capsulatum* as shown by cultural techniques and variance in sensitivity to specific antifungal agents. Although there is a broad clinical spectrum associated with progressive disease, disseminated histoplasmosis and chronic pulmonary histoplasmosis are the clinical types of major importance.[1,2,5,8,10,14]

Disseminated histoplasmosis should be suspected in patients with obscure fevers; lymph node, hepatic and splenic enlargements; and with a history of possible exposure. The diagnosis is materially aided by a positive skin test, a significant complement-fixation titer, and by culturing the bone marrow, the blood, and the sputum. The Cooperative Study Group on Mycoses of the U. S. Public Health Service recently reported a mortality of 80 per cent in a series of twenty-five untreated cases of disseminated histoplasmosis.[14]

The history of the patients with chronic pulmonary histoplasmosis resembles that of tuberculosis closely in that there is weight loss, recurrent fever, cough and hemoptysis, expectoration and gradual downhill course. The chest x-ray findings are practically identical. An infrequent patient with chronic pulmonary histoplasmosis will experience spontaneous remissions such as may be seen in tuberculosis. This is usually a fluctuation of exudative disease whereas the chronic components such as cavitation tend to persist. Tuberculosis co-exists with histoplasmosis in about 10 per cent of chronic pulmonary cases.[13] Physical findings are of relatively little help in this disease.

As is true of tuberculosis, cultural or histological demonstration of the organism is the major factor in diagnosis. All tissue obtained from patients

suspected as having a deep mycosis should be stained and cultured for fungi. The mucus in sputum interferes with the special stains, and digestion of sputum kills the organisms. Tissue that has been fixed in formalin for many years can still be sectioned and stained with special techniques to reveal the yeast bodies. The most useful stain is the Gomori modification of the methenamine silver stain. The Periodic Acid Schiff stain is helpful, but other structures in the tissues may react and cause confusion. The standard Hemotoxylin and Eosin stain is of little value. A useful rapid screening procedure is the use of polarized light microscopy.[8]

Recently, the co-operative study of the U. S. Public Health Service has reported on 85 untreated chronic pulmonary cases. Of these 74 per cent were either dead or physically disabled to the extent of 50 per cent or more at the end of an average of 3.6 years of followup.[14]

The differential diagnosis of this disease is important. The diseases that may be confused with it are sarcoidosis, tuberculosis, blastomycosis, actinomycosis, acute or chronic pneumonias, influenza, and many others, including cancer. The disease is a "great imitator." Mucocutaneous ulcers proven to be due to histoplasmosis indicate disseminated disease. The disease can produce pleurisy with effusion, bone and joint lesions, meningitis, gastric ulcers, diffuse lymphadenopathy, hepatomegaly, splenomegaly, chronic inflammatory renal disease, cold abscesses, and adrenal insufficiency.

In summary, a few pertinent points regarding diagnosis should be emphasized. A history of exposure, such as living in a highly endemic area, is helpful but lack of this doesn't exclude the disease. The disease resembles tuberculosis closely but if tuberculosis has been excluded, cultural studies for *Histoplasma capsulatum* should be done on sputum, blood, and bone marrow. Multiple cultures are essential. Complement-fixation and skin tests are useful screening tests but when negative do not rule out the disease in the individual patient. If the complement-fixation test is positive, this is helpful, but demonstration of the organisms by cultural or histological techniques is essential to an accurate diagnosis. Investigation of other members of the family or group may prove helpful. Culturing the organism from a possible source of exposure is also helpful. All tissue from patients with suspected histoplasmosis should be carefully studied by suitable cultural and histological techniques. Lastly, as with many diseases, a high index of suspicion is a definite asset.

The cornerstones of medical management are those which are of value with tuberculosis; that is, rest, adequate nutrition, and specific chemotherapy.[8] A rare patient with chronic pulmonary disease will improve on rest and good nutrition alone. In chronic pulmonary or disseminated disease, the mortality and progression rates are so high that specific therapy is necessary.

A period of observation may be necessary to determine activity. In the management of acute benign cases, an observation period of two to four weeks is advisable to determine if the disease will subside without specific drug treatment. The criteria used in deciding on specific antifungal treatment are: the presence of cavitation, positive sputum, x-ray progression; evidence of disseminated disease, such as palpable spleen, positive blood and bone marrow cultures; mucocutaneous ulcers; a progressive downhill course; high fever; severe cough; hemoptysis; positive urine cultures; and positive cultures from resected tissue. Rarely, a patient with acute benign disease, which is subsiding slowly, may be given specific treatment to speed recovery.

Amphotericin B* is the best antifungal agent that is currently available.[4,7,8,12,13] Amphotericin B is a polyene antibiotic produced by a streptomyces isolated from a soil sample taken from along the Orinoco River in South America. It is relatively insoluble and is not absorbed from the gastrointestinal tract. It must be given by the intravenous route in a dilute solution. Treatment is begun with 25 mgm. in 500 to 1000 cc. of 5 per cent glucose in water, administered slowly over a six-hour period. The daily dosage is increased by increments of 5 mgm. as tolerated until a total daily dose of 1 mgm. per kilogram of body weight is reached. The frequency may then be decreased to three times a week.

Side effects such as chilling and fever, headache, anorexia and some nausea are frequent and annoying but not dangerous. Tolerance rapidly develops and these are relatively mild in the majority of cases. These reactions can be controlled by the exhibition of acetylsalicylic acid and adrenoster-

*Squibb's Fungizone.

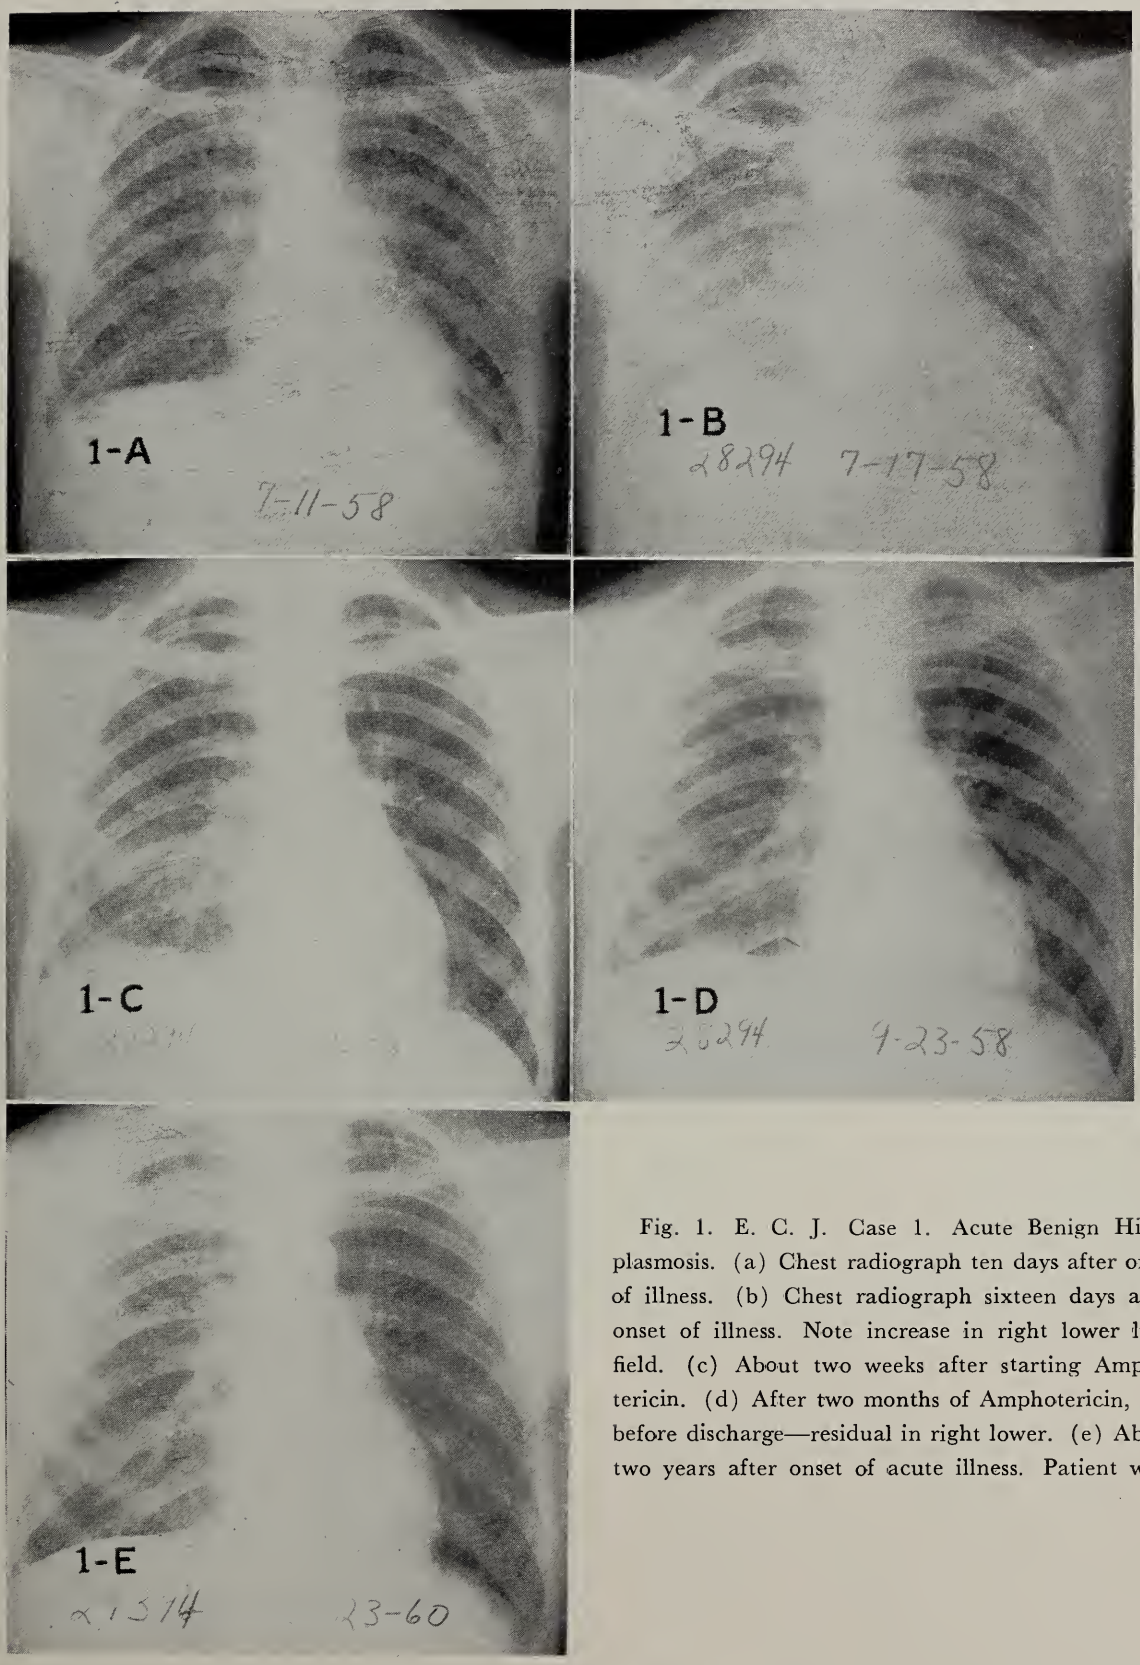

Fig. 1. E. C. J. Case 1. Acute Benign Histoplasmosis. (a) Chest radiograph ten days after onset of illness. (b) Chest radiograph sixteen days after onset of illness. Note increase in right lower lung field. (c) About two weeks after starting Amphotericin. (d) After two months of Amphotericin, just before discharge—residual in right lower. (e) About two years after onset of acute illness. Patient well.

oids. The steroids may be administered intravenously in the same fluid as the Amphotericin. Elevation of the blood urea nitrogen (BUN) may occur later in the course of therapy. This may be helped by forcing fluids and occasionally by decreasing dosage in these patients. If the BUN does not go above 40, treatment may be safely continued. Two to four weeks after discontinuance of Amphotericin, the BUN returns to normal. This BUN elevation is apparently due to a direct effect of the drug on the kidney. The phenolsulfonphthallien excretion and the urea clearance are also impaired. An occasional patient will experience a transient periphlebitic inflammatory reaction which is easily controlled by administering adrenosteroids and heparin in each intravenous treatment. It is advisable to avoid using the same vein on consecutive treatment days. Rashes have been observed. Hypersensitivity angiitis with polymyositis has occurred infrequently. The agent is an antibiotic and therefore hypersensitivity must be expected. Mild hypochromic anemias may develop, particularly in patients with elevated BUN. These usually respond to iron therapy.

The optimal duration of treatment is unknown. However, it should be continued for a period of at least four months and even then discontinuance in severe disease may result in relapses. Usually, the sputum cultures become negative within a two-to-four week period. Clinical improvement with decrease of sputum, cough, and some improvement by x-ray occurs more gradually beginning within a two-month period. X-ray improvement is much slower and less striking than the clinical and sputum improvement. Apparently, the longer Amphotericin therapy is continued, the less likely relapses will occur. A relatively high percentage of sputum, x-ray and clinical relapses occurs if treatment is discontinued at eight weeks or less. Relapses are observed even after five to six months of Amphotericin therapy, particularly if large amounts of necrotic debris persist.

Because this treatment must be considered primarily suppressive, surgery plays an important part in the management of chronic pulmonary histoplasmosis. Surgery is usually considered at the eight-to-twelve week period of Amphotericin therapy. Amphotericin should be continued for at least two to four weeks after surgery.

The patient tolerance of this treatment is poor due to the prolonged intravenous courses necessary, the side effects, and the slow x-ray response. The rapport between the doctor and the patient plays an extremely important part in continuing the treatment.

Other drugs are being tested but these are not too promising as yet. Adrenal insufficiency must be kept in mind and suitable therapy instituted when indicated.

Two case histories and reproductions of selected radiographs are included here to illustrate some of the points discussed above.

Case Histories

Case 1.—E. C. J., a seventeen-year-old white farm youth, was well until a sudden onset of chills, fever, cough, malaise, anorexia one week after assisting his father and another man in cleaning a chicken house. The two men were also ill but for a much shorter time and less severely. The family history is negative for tuberculosis. In spite of penicillin, the boy continued to cough, have fever, malaise, weight loss, and developed pleuritic pain in the right lower chest.

On admission to the Missouri State Sanatorium two weeks after onset of symptoms, he appeared obviously toxic and malnourished, with fever up to 103°. The physical examination was otherwise normal except for some lag, impaired resonance and depressed breath tones over the lower right chest. Lymph nodes, liver and spleen were not remarkable.

Laboratory Findings.—Abnormal and pertinent negatives only—WBC 15,000, 66 per cent polys with left shift; blood count otherwise normal and urinalysis negative. Repeated cultures of sputum, bone marrow, and blood for *Histoplasma capsulatum* and M. Tuberculosis negative. The histoplasma complement-fixation was negative on admission but became positive eighteen days after admission with mycelial antigen of 1/16 and yeast phase antigen of 1/128. Subsequently, the yeast phase titer rose to 1/256 and the mycelial phase antigen was 1/8. Repeated intermediate and second strength PPD skin tests were negative. (Boy's father—positive Histoplasmin complement-fixation and skin test.) Histoplasmin skin test—induration 16 mm., erythema 18 mm., positive.

Hospital Course.—Because of the continued severe febrile illness and increasing x-ray findings (Fig. 1) and negative tuberculins, Amphotericin B intravenously was begun two days after admission and continued for two months after which the patient was discharged to continue to rest at home for three months more before returning to school full time. He improved remarkably within a seven-day period (Fig. 1—rapid x-ray improvement). At the time of the last chest radiograph on June 23, 1960, he was completely well.

Comment.—This illustrates a severe type of acute benign disease with perhaps a speeding of recovery by Amphotericin therapy.

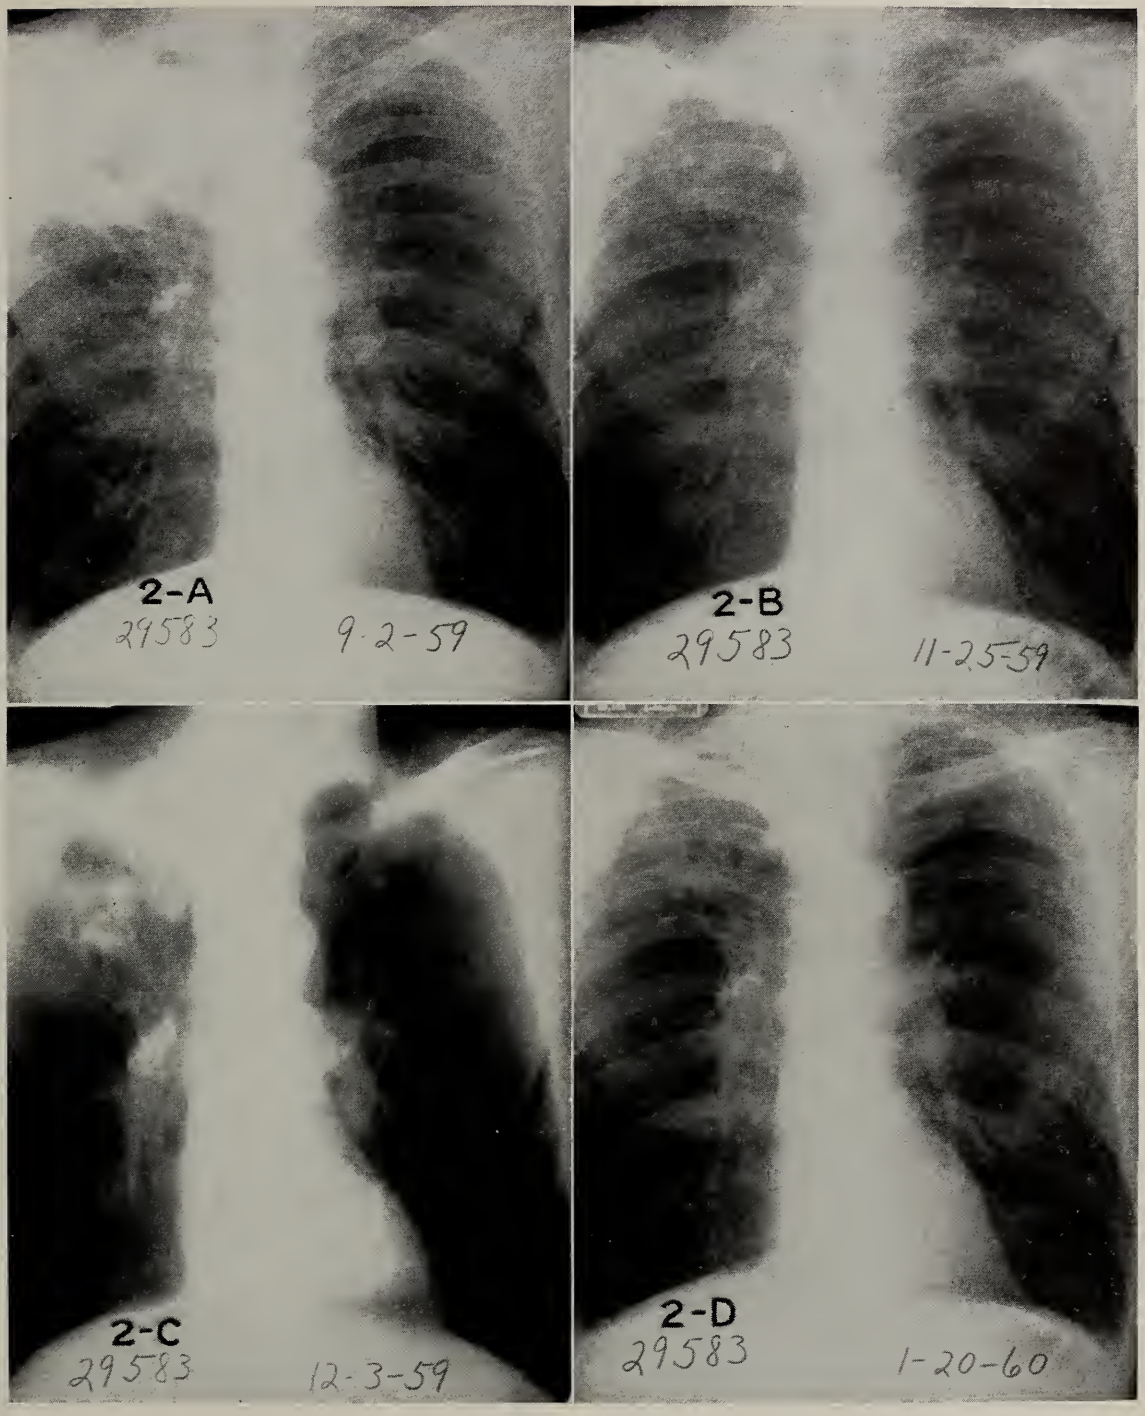

Fig. 2. H. L. H. Case 2. Chronic Pulmonary Histoplasmosis. (a) Posteroanterior chest radiograph one month before beginning Amphotericin. (b) Posteroanterior chest radiograph after one and one-half months of Amphotericin. Residual cavitation. (c) Planigram approximately two and one-half months of Amphotericin B. (d) Posteroanterior chest radiograph one day before right upper lobectomy.

Case 2.—H. L. H., a white farmer, aged fifty-nine, with a negative family history for tuberculosis, was admitted to the sanatorium after a two-month history of a "flu-like" illness with recurrent fever, malaise, cough, purulent expectoration and weight loss of 20 pounds. A chest radiograph was interpreted as showing "pulmonary tuberculosis." The past medical history revealed typhoid fever as a child, previous ulcer symptoms, transient jaundice three years before without recurrence.

The systemic review was noncontributory.

The physical examination was normal except for malnutrition.

Laboratory Findings.—Normal CBC, urinalysis, and fasting blood sugar. Numerous sputum studies for tuberculosis (smear and culture) all negative. BUN, serum bilirubin, BSP, cephalin flocculation and thymol turbidity all normal, albumin 4.4 gm., globulin 3.3 grams. Nine sputum cultures positive for *Histoplasma capsulatum*. Intermediate PPD positive. Histoplasmin skin test positive. Complement-fixation test—mycelial 1/16, yeast 1/64 on admission remained positive on numerous tests with gradually decreasing titer and became negative immediately after right upper lobectomy.

Course in Hospital.—Patient was observed on modified bed rest for five weeks, and then intravenous Amphotericin was begun. He experienced mild fever and chilling at first and later BUN elevation to 26.3 mgm. per cent. Sputum decreased within one month to almost nothing, patient's fever disappeared within two weeks. As may be seen in Figure 2, the chest radiograph revealed remarkable improvement, but residual cavities persisted. A right upper lobectomy was performed after three and one-half months of Amphotericin therapy. The sputum findings became repeatedly negative two weeks after initiation of Amphotericin and remained so for a total of eighteen negative cultures up to the time of discharge about three weeks after surgery and one week after discontinuance of Amphotericin. At time of discharge, the patient was apparently well. He was to increase his physical activity gradually and return to work six months after discharge. A follow-up radiograph (not shown) two months after discharge revealed excellent result. The surgical specimen revealed atelectasis, a 2 cm. cavity and several small inspissated cavities. Methenamine silver stains were positive but cultures from the resected tissue were negative.

Comment.—This illustrates the management of a patient with chronic pulmonary histoplasmosis with Amphotericin therapy and surgical resection with a fine result.

Summary

Histoplasmosis is an important medical problem. As with tuberculosis, the diagnosis rests on the demonstration of the organism by cultural or histological techniques.

Rest, good nutrition, and specific antifungal chemotherapy are cornerstones of medical management of serious types of disease such as chronic pulmonary and disseminated histoplasmosis. Amphotericin B is the best specific therapy available at present, but it is primarily suppressive. Patient acceptance of Amphotericin B therapy is only fair. When feasible, excision of narcotic debris under an Amphotericin "umbrella" will decrease the relapse rate significantly.

Surgical Treatment of HISTOPLASMOSIS with Case Reports

JOHN W. POLK, M.D.
and ALAN H. BAILEY, M.D.
Mt. Vernon, Missouri

PULMONARY histoplasmosis, an isolated phase of generalized histoplasmosis, was considered a rare disease in 1945. Even though the organisms has been isolated in 1934[1] from a clinical case, the clinical manifestations and pathogenesis of this disease were not fully described. Chronic progressive histoplasmosis has been described by Bunnell and Furcolow[2] and Johnson and Batson[3] in 1958 with Sutliff and his co-workers[4] later presenting cases comparable to this. Focalized pulmonary histoplasmosis was presented by Forsee and his co-workers in 1953.[5] We presented two groups of cases in 1956[6] and 1957,[7] attempting to show that pulmonary histoplasmosis can mimic almost any disease which is encountered in the lungs and that in most of these cases, pulmonary histoplasmosis cannot be ruled out without finding the etiologic agent *Histoplasma capsulatum*. In our two previous reports, we also stated that we believed pulmonary resection offered an adequate method for treatment in selected cases. It is the

Dr. Bailey is Assistant in Surgery, Missouri State Sanatorium, Mt. Vernon, Missouri.

purpose of this paper to reiterate our indications for pulmonary resection and to comment on our experiences with Amphotericin B in the treatment of several cases undergoing surgical resection after having been administered this drug.

Indications for Resection

We had previously commented that two considerations were of utmost importance when considering the treatment of pulmonary histoplasmosis: (1) that establishing the diagnosis of pulmonary histoplasmosis may be long and tedious; (2) that if the patient has not localized his disease to a portion of the lung, the prognosis, up until recently, has been very poor. If these factors are realized surgical resection alone or with the coverage offered by Amphotericin B seems to offer excellent therapy with certain forms of this disease.

Due to the paucity of cases reported (excluding focalized coin lesions), the indications for resection are not too clear. We have utilized many of the indications which were established in the surgical treatment of pulmonary tuberculosis as a guide to our selection of cases with histoplasmosis.

Indications for Surgery

1. Coin lesions
2. Large solid mass (over 6 cm. in diameter)
3. Right middle lobe syndrome
4. Bronchiectasis
5. Bronchial stenosis
6. Acute lung abscess
7. Destroyed lung
8. Empyema with or without bronchopleural fistula
9. Cavitary histoplasmosis

Discussion

Resection of localized histoplasmosis usually occurs because a definite diagnosis cannot be established. Since it has been definitely shown that bronchogenic carcinoma is indistinguishable from this, exploratory thoracotomy and surgical removal is mandatory. Because of the fact that approximately 30 per cent of these patients will have tuberculomas, the activity of which is unknown, and because the two diseases can occur in the same coin lesion, we prefer to put these patients on antituberculosis therapy at least five days prior to their removal. On this routine, we have had no spread of the pulmonary histoplasmosis or tuberculosis.

The large solid mass mentioned above is a fairly rare form of this disease. When such masses occur, they are completely indistinguishable from a bronchogenic carcinoma. Bronchoscopy has been of no value in aiding with a diagnosis of histoplasmosis in this form of the disease. In all our cases, the diagnosis was established after lobectomy. It is worth noting that at the operating table these lesions feel hard and are most commonly located in the center of a lobe.

The right middle lobe syndrome is usually diagnosed from the history, complement fixation tests, and histoplasmin skin tests. In none of these cases have we been able to isolate the organism from the sputum prior to surgery, and the surgery is often performed several months or years after the active process has subsided. As in other diseases producing the middle lobe syndrome, histoplasmosis is caused by the extensive lymph node involvement around the bronchus.

Histoplasmic bronchiectasis seems to be a fairly rare disease also, excluding the bronchiectatic right middle lobe which occurs with the syndrome. In the cases in which we have done resection, the diagnosis has not been made prior to surgery, resection having been proposed because of extensive saccular bronchiectasis. It is worth noting from the history of two of these patients, however, that hemoptysis was a chief complaint, and in both of them the amount of hemoptysis was over twenty ounces. In the future, we would suspect this disease in a patient having extensive bronchiectasis with large recurrent hemoptysis and a

strongly positive histoplasmin skin test.

We have been able to demonstrate only one case with true bronchial stenosis as a result of this disease compared to numerous reported cases of stenosis with tuberculosis as the etiologic factor. A case report will be given.

Acute lung abscess was not in our list of indications for surgical resection until the past year. Prior to this, we had considered that other organisms were responsible for the abscess and that *Histoplasma capsulatum* was a contaminant. Because of several cases in which we have done resection and from which only that organism could be cultured, we have included it in this list. We have also considered this in our preoperative diagnosis on patients in whom we have been unable to culture any specific organism and in whom there has been no demonstrable improvement after extensive broad spectrum antibiotic therapy. Lobectomy appears to be the procedure of choice in this group of cases.

Destroyed lung is listed in our series of cases for two reasons: (1) the lung may be destroyed by histoplasmosis alone although this appears to take several years with the progressive form of this disease; two cases, however, have been subjected to pneumonectomy where the disease appeared to be acute and pneumonic in type; (2) resection has been done in several cases with destroyed lung from which both acid-fast organisms and the organism *Histoplasma capsulatum* were cultured. In three of these cases, the diagnosis of pulmonary tuberculosis had been made alone because of positive sputum prior to resection.

Histoplasmic empyema, with the organism *(Histoplasma capsulatum)* having been cultured from the empyema fluid, is rare. In only two cases have we been able to prove this. In one case, the empyema occurred following a destroyed lung with bronchopleural fistula. In the second, the empyema was localized to the right lower lobe area. A bronchopleural fistula was also demonstrated in this case. Treatment of this would appear to us to vary with the selection of cases.

Cavitary pulmonary histoplasmosis is the most frequent form of this disease for which we have performed surgical resection. Prior to the advent of the antifungal agents, we had advocated lobectomy for this type of disease. With the use of Amphotericin B, however, our concept has changed, and we are able to list several factors which we believe are important prior to surgical resection for the cavities.

First, it is with the cavitary form of the disease that the organism is most frequently and easily demonstrated. Thus, a diagnosis of histoplasmosis can be definitely established before resection. When this occurs, we believe that we are justified in treating the patient with Amphotericin B prior to surgical resection even though there are numerous side effects to this drug. We also believe it is worthwhile waiting for the sputum to be converted to a negative phase by this form of treatment. This form of treatment appears to cause regression in the infiltrative process surrounding the cavitary component. It has been our experience, however, that in the chronic, cavitary phase of this disease that this drug alone will not close cavities over 3 or 4 cm. in diameter. In none of the cases which had Amphotericin B prior to resection has there been a spread of the disease demonstrable following surgery.

Several case reports concerning this form of disease will be given and a case report which had a spread ten months postoperatively will also be included. This case with the spread did not have Amphotericin B coverage at the time of initial resection.

Case Reports

Case 1 (Large solid mass).—A white man, aged fifty-nine, was admitted to the Missouri Sanatorium on December 12, 1956. He stated that he had had several colds in the winter of 1955 and 1956, developing productive cough five months prior to admission. In the fall of 1956, he developed severe pain in the right chest, and a roentgenogram revealed a dense mass in the right upper lung field. He was admitted to the Missouri State Sanatorium by his local physician, believing that

this mass represented a carcinoma or tuberculous process.

Past history was negative. Physical examination was non-contributory.

The vital capacity was 5,017 cc. and maximum breathing capacity 124 liters per minute. Routine sputum examinations included cultures negative for AFB. The histoplasmin skin test was strongly positive and the tuberculin skin test was negative. Bronchoscopy was performed on December 14 and all studies wese negative for malignant cells and acid fast organisms. On December 20, right upper lobectomy was performed. Frozen section at the time of surgery failed to reveal a malignant lesion. After a relatively uneventful postoperative course, he was discharged on January 16, 1957 to resume his normal occupation. PAS stain and methenamine silver stains of the resected lung tissue revealed *Histoplasma capsulatum*.

(In several cases which we have seen such as this, it was necessary to perform lobectomy prior to making diagnosis).

stenosis of the right upper lobe bronchus. Smears from this area were negative for malignant cells.

Right upper lobectomy was performed on October 20. Patient was discharged October 27 after an uneventful postoperative course. Pathological sections of the lung showed a multiloculated cyst, the largest measuring 6 cm. in diameter. From this larger cyst were numerous connective openings to smaller cysts. Section of the upper lobe bronchus showed it to be obstructed and completely obliterated by fibrous tissue. Unfortunately, cultures of the resected specimen were not done for fungi. PAS stain and methenamine silver stain, however, revealed numerous organisms which were identified as Histoplasma capsulatum.

The patient has now been followed for over four years and has had no recurrence of his histoplasmosis. Seriological studies for histoplasmosis have been negative since six months after surgery. Histoplasmin skin test remains strongly positive however. The patient has returned to his normal occupation as a truck driver.

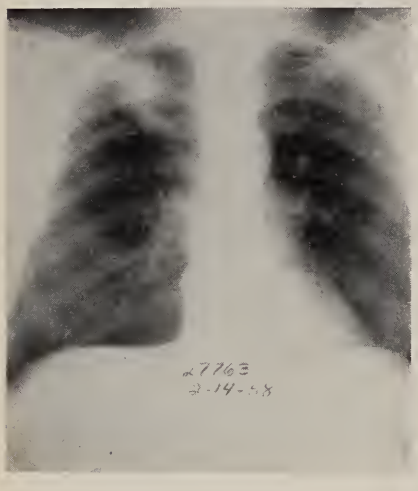

Fig. 1. Case 1. A white man, aged fifty-nine, large solid lesion.

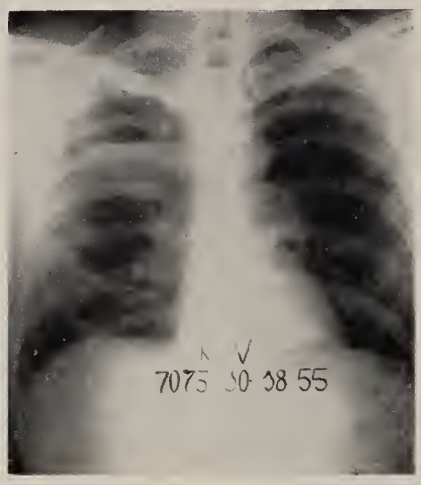

Fig. 2. Case 2. A white man, aged thirty-nine, with large cystic cavities and bronchial stenosis. (Used by permission of *Journal of Thoracic Surgery*, C. V. Mosby Company).

Fig. 3. Case 3. A white man, aged fifty-one, destroyed right lung. (Used by permission of Chas. C Thomas. Publisher, from the book "Histoplasmosis" by H. C. Sweany, M.D., No. 486).

Case 2.—A white man, aged thirty-nine, had been seen on October 18, 1955 at Burge Hospital, Springfield, dyspnea and malaise were also noted. Even though the Missouri. He stated that in September, 1955, he had developed severe cold, pain in the right chest, and sensation of pressure in the right chest. Exertional above symptoms persisted, he worked until October 15. Roentgenogram at this time revealed a large cystic lesion containing fluid in the right upper lung field.

Past history was non-contributory.

Physical examination revealed fine moist rales over the right upper lung field. Blood pressure was 176/70. Complete blood studies were normal. Histoplasmin skin test was strongly positive. Tuberculin skin test was negative. Several sputum examinations were reported negative for acid fast organisms. Bronchoscopy revealed

Case 3.—A white man, aged fifty-one, was admitted to the Missouri State Sanatorium on January 3, 1958, stating he had felt well until December, 1957, when he was diagnosed as having influenza. At this time, he had severe cough, shortness of breath, and raised thick yellow sputum. He denied hemoptysis. He also stated that he had lost approximately 20 pounds of weight in the past three months. Symptoms continued. After a radiograph of the chest was made, he was admitted to the Missouri State Sanatorium.

Past history was noncontributory.

Physical examination revealed an emaciated, acutely ill, white man, who appeared to be short of breath. There were moist rales over the right upper lung field and and there was a wheezing over the right upper lung field. Remainder of the physical was noncontributory. CBC and urinalysis were normal. The tuberculin skin

test was negative. Histoplasmin skin test was positive. Sputum cultures were negative for AFB but repeatedly positive for Histoplasma capsulatum.

Bronchoscopy was done on January 21 and revealed redness of the bronchial mucosa on the right. After the diagnosis of histoplasmosis had been established by repeated sputum cultures, the patient was placed on Amphotericin B. Therapy was given three times weekly until the maximum of 65 mgm. had been reached. On this medication, his cough improved but his sputum never converted to the negative status. On May 6, right pneumonectomy was performed because of destroyed right lung. The only areas not involved were the basal segments which were markedly emphysematous and over-distended. Following pneumonectomy, the patient's sputum was continuously negative for *Histoplasma capsulatum* and Amphotericin B was continued until his discharge on May 28.

This patient did extremely well until October 2, when he developed a pneumonia in the left lung and he expired at the University Hospital, Columbia, Missouri, on October 30, 1958. Autopsy revealed lobar pneumonia, left lower lobe, and one small fibrocaseous nodule in the left lung in which the organism Histoplasma capsulatum was demonstrated on special stain.

This is one of the few cases in which the sputum did not convert to the negative status on Amphotericin B therapy.

Case 4.—A white man, aged fifty-nine, was admitted to the Missouri State Sanatorium on January 28, 1958, with chief complaint of shortness of breath and pain in the chest. He had had numerous x-rays prior to this at various hospitals and had never been found to have pulmonary disease. Radiograph taken in early August, 1958, showed bilateral infiltration and cavitation and the patient was admitted to the sanatorium.

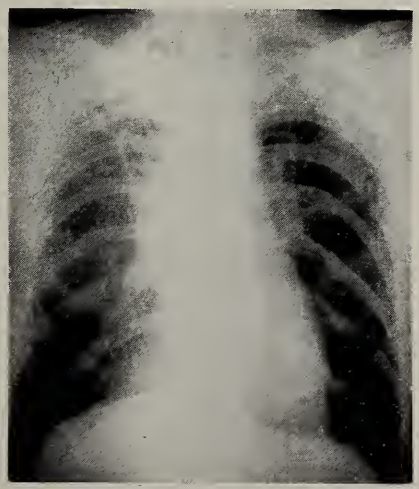

Fig. 4. Case 4. A white man, aged fifty-nine, bilateral cavitation, histoplasmosis and tuberculosis.

At the sanatorium, both the tuberculin and histoplasmin skin tests were strongly positive. Repeated cultures of the sputum were positive for acid fast organisms and Histoplasma capsulatum. The patient was placed on streptomycin, 1 gram daily, INH, 100 mgm. tid, and PAS, 12 grams daily. He also received Amphotericin B from March 30, 1959 to July 29, 1959, intravenously three times weekly.

On the above regimen, the sputum became negative for both acid fast organisms and Histoplasma capsulatum. On August 3, because of persistent cavitation in the right apex, an apical posterior segmental resection was performed. The patient had an uneventful postoperative course and was discharged November 17, 1959, receiving antituberculous therapy. No Amphotericin B was utilized postoperatively.

This case demonstrates how both tuberculosis and histoplasmosis mimic each other and at times both diseases will have to be treated concomitantly.

Conclusions

Pulmonary histoplasmosis may mimic any disease which occurs in the lung. This is especially true when paralleling the course of this disease with the pathological processes of tuberculosis. That the two diseases occur simultaneously has been well documented.

In selected cases, pulmonary resection offers an excellent method in the treatment of chronic pulmonary histoplasmosis. We believe Amphotericin B will prevent spreads postoperatively, and it is possible, in the future, that patients who have been denied surgical therapy may become candidates for this definitive type of treatment.

JAMES C. MELBY, M.D.
Little Rock, Arkansas

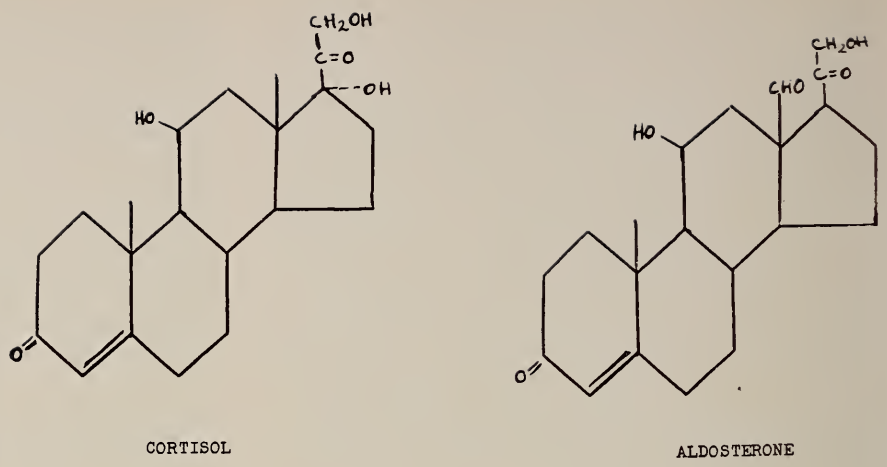

Fig. 1. The most important corticosteroids secreted by the human adrenal cortex, cortisol and aldosterone. Note the absence of a hydroxyl group on C_{17} and addition of an aldehyde group on C_{18} on the aldosterone molecule.

ANIFESTATIONS of adrenocortical dysfunction are usually obvious. Laboratory confirmation consists in the demonstration of abnormal adrenocortical hormone production. Nonspecific tests may not be relied upon consistently so that decisions regarding surgical extirpation of the adrenals and/or lifetime hormone replacement must rest firmly on measured alterations of blood hormone concentrations and/or urinary metabolite excretion. Specific assessment is essential in the so-called "borderline" disorders. Representative of these conditions are obese women with hirsutism, hypertensive plethoric individuals with diabetes and adolescents with truncal obesity and striae. The examples cited are commonly encountered and present certain features suggesting adrenocortical hyperfunction.

A number of individuals with renal salt wasting, hypotension and hyperpigmentation are virtually indistinguishable from patients with classical Addison's disease. On the other hand, a number of patients have been reported whose appearance is normal but who manifest acute adrenocortical insufficiency when subjected to stress.

Over the past fifteen years, intensive efforts to apply methods for estimation of adrenocortical hormone production has been made. A few of these methods are suitable for routine laboratory use. This report will confine itself to the application and interpretation of some of these procedures.

Chemical and Physiological Considerations

Some 46 steroids have been isolated from adrenocortical tissue or adrenal venous effluent. Most have not been found in adrenal vein blood and thus represent precursors or metabolic transformation products.

Corticosteroids—C-21 steroids with three or more oxygen atoms. These are formed exclusively in the adrenals.

Progestins—C-21 steroids with less than three oxygen atoms having progestational activity.

Androgens—C-19 steroids with an oxygen atom of C-17 (17-oxo- or 17-ketosteroids and precursors) having androgenic activity.

Estrogens—C-18 steroids with estrogenic activity.

From the Department of Medicine, University of Arkansas Medical Center, Little Rock, Arkansas, Dr. Melby is Assistant Professor of Medicine and Biochemistry at the University of Arkansas.

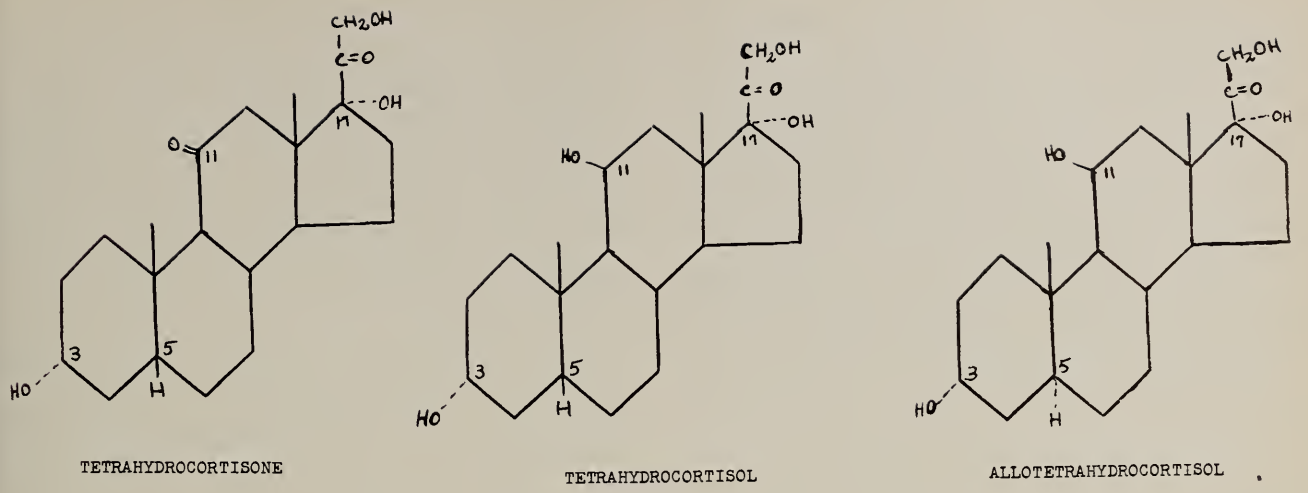

Fig. 2. Urinary metabolites of cortisol which retain the dihydroxyacetone side chain at C_{17} and give a positive Porter-Silber reaction (17-OHCS).

The Corticosteroids

Two corticosteroids (C-21), cortisol and aldosterone, account for most of the biological activity of the adrenal cortex (Fig. 1).

Cortisol is the predominant corticosteroid product of the normal human adrenal cortex.[1] It is anti-inflammatory and a regulator of "organic" metabolism (protein and carbohydrate) hence is referred to as a glucocorticoid. It circulates in the blood in a concentration of from 4-30 micrograms/100 ml. plasma. The plasma concentration of cortisol follows a definite diurnal rhythm with a peak in the morning and trough in the evening. The daily production of cortisol averages approximately 20 mg. A continuous infusion of corticotropin (ACTH) results in a maximal peripheral blood concentration of cortisol within four hours which thereafter remains constant for the duration of the infusion. Such maximal constant stimulation results in the production of 150-250 mg. of cortisol and cannot be further augmented by increasing the dose of corticotropin.[2] The average daily production rate of cortisol agrees with the replacement requirements of Addisonian and of totally adrenalectomized patients amounting to 20 to 30 mg. per day.

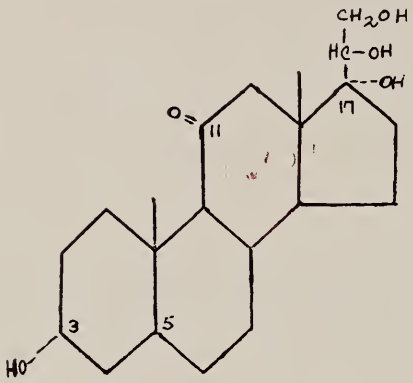
Cortisol is enzymatically inactivated in the liver by reduction to a number of metabolites which are rapidly conjugated with glucuronic acid to form water-soluble glucuronides which are excreted in the urine.

The 17-Hydroxycorticosteroids (17-OHCS)

Two major groups of metabolites are measured by methods currently employed in the clinical laboratory. In the first group reduction of the first ring of the steroid nucleus occurs without alteration of the C-17 side chain. These cortisol metabolites are known as Porter-Silber chromogens or 17-hydroxycorticosteroids (17-OHCS). The C-17 side chain reacts with phenylhydrazine to form a yellow compound which is easily measured.[3] It is this reaction which has enjoyed the widest clinical usage, as both cortisol in plasma and urinary metabolites may be measured. These compounds in urine (tetrahydrocortisone, tetrahydrocortisol and allotetrahydrocortisol) account for 20 to 30 per cent of the urinary metabolites of cortisol (Fig. 2).

The 17-Ketogenic Steroids

The second group of metabolites (20-40 per cent) (cortols and cortolones) are reduced as described above but, in addition, the C-20 carbonyl

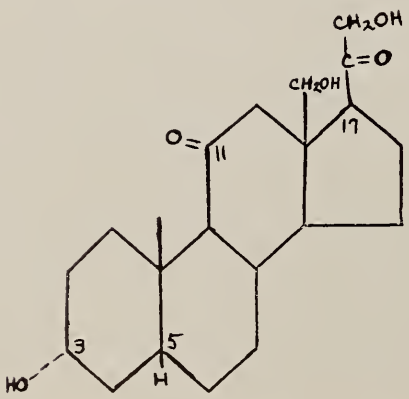


group is reduced to form a C-17 glycerol side chain (Fig. 3).

When both groups of metabolites are treated with sodium bismuthate, the C-17 side chain is oxidized to form 17-ketosteroids. Norymberski first applied this procedure[4] and referred to these steroids as 17-ketogenic (17-KGS).

In the Norymberski procedure for 17-KGS, the Zimmerman reaction[5,6] is employed for 17-ketosteroids (17-KS) using m-dinitro-benzene to form a violet colored compound.

The Electrolyte-Active Hormone



Aldosterone is the most potent hormonal regulator of sodium and potassium metabolism and is secreted at a rate of 150-300 micrograms per day. Its plasma concentration varies from 0.04 to 0.08 micrograms/100 ml. Aldosterone secretion is stimulated by a reduction of intravascular fluid volume, potassium loading and transiently with ACTH. Aldosterone stimulating hormone (glomerulotropin) is a lipid complex originating in the posterior hypothalamus, possibly the pineal gland and subcommissural body.[7]

β-CORTOLONE

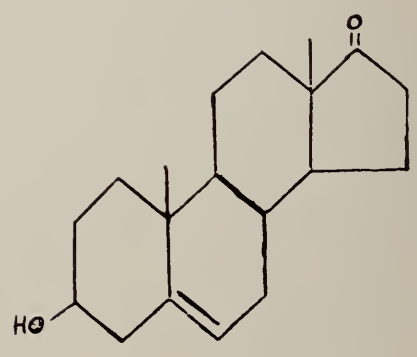


Fig. 3. B-cortolone is the predominant cortisol metabolite having a glycerol side chain at C_{17}. It does not give a positive Porter-Silber reaction but is included in the 17-KGS.

At the present time, all methods for the measurement of aldosterone or its metabolites in the urine are tedious because partition chromatography on filter paper using at least three solvent systems is required. The method of Neher and Wettstein[8] or a suitable modification is generally employed for a fraction representing 5 to 10 per cent of the daily production. Interestingly, the "pH 1-3-oxo-conjugate" is biologically active. The possibility of a simpler method was suggested by the isolation of a "tetrahydro" metabolite by Ulick, Laragh, and Lieberman.[9] A method for the chemical estimation for the "tetrahydro" metabolite of aldosterone has been successfully applied to urine in this laboratory.[10] It has been possible to extract this substance after glucuronidase hydrolysis from as little as a 50 ml. aliquot of urine and apply the residue to paper in a single Zaffaroni-type solvent system. Using the augmented Porter-Silber reaction of Lewbart and Mattox, very small quantities are readily measured. Values of from 50 to 150 micrograms per day are normally excreted. This value may be trebled on sodium restriction. The method requires only one working day (Fig. 4).

'TETRAHYDRO' METABOLITE OF ALDOSTERONE

Fig. 4. This compound is excreted as a glucuronide conjugate and may be quantitatively the most important of aldosterone metabolites.

DEHYDROEPIANDROSTERONE

Fig. 5. Dehydroepiandrosterone is the principal precursor of the urinary 17-KS, androsterone and etiocholanolone.

Adrenal Androgens (The 17-Ketosteroids)

Dehydroepiandrosterone (DHEA) is weakly androgenic and exists in the peripheral blood in higher concentration than other steroid hormones. Its production rate has been estimated to average 55 mg. per day. DHEA appears to be the principal precursor of the urinary 17-KS (androsterone and etiocholanolone). DHEA is exclusively of adrenal origin. Its precursor, 17α-OH-pregnenolone, may be secreted into the circulation where it is oxidized to DHEA (Fig. 5).

TABLE I. URINARY EXCRETION IN MG. 24 HOURS

17-OHCS	17-KGS	17-KS	Aldosterone (pH-1-3-oxo conjugate)	Tetra-hydroaldosterone
3-12 (both sexes)	5-26 (males) 4-17 (females)	8-23 (males) 5-18 (females)	.002-.016	.05-.15

It is unfortunate that the urinary 17-KS procedure is used as a parameter of adrenocortical function in any of the adrenal disorders except those characterized by virilism. The urinary 17-KS excretion is the least reliable index of adrenocortical function.

In Table I are listed normal values for urinary excretion of 17-OHCS, 17-KGS, 17-KS, aldosterone (pH 1-3-oxo-conjugate) and tetrahydroaldosterone.

Classification of Adrenal Cortical Dysfunction

I. *Hypofunction of the Adrenal Cortex*

- A. Primary—panhypocorticalism—underproduction of cortisol, aldosterone and adrenal androgen.
  - 1. Acute—Addisonian crisis, adrenal "apoplexy" and (?) Waterhouse-Friderichsen Syndrome.
  - 2. Chronic—Addison's disease
    - (a) Complete or classical
    - (b) Partial or "limited" adrenal cortical reserve
- B. Secondary hypocorticalism—mainly cortisol undersecretion due to hypopituitarism
  - 1. Panhypopituitarism
  - 2. Inhibition of adrenocorticotropin (ACTH) synthesis and/or release during and after administration of cortisol or its synthetic analogs
- C. Primary isolated corticotropin deficiency
- D. Inborn errors of steroid metabolism—variable capacity for secretion of cortisol due to relative deficiencies in adrenal cortical hyperplasia
- E. Accelerated cortisol catabolism—thyroid storm

II. *Hyperfunction of the Adrenal Cortex*

- A. Cushing's syndrome of cortisol overproduction due to:
  - 1. Bilateral hyperplasia (80 per cent) or unilateral neoplasia (20 per cent)
  - 2. Bilateral hyperplasia associated with pituitary tumor and pigmentation (primary ACTH excess?)
  - 3. Bilateral hyperplasia associated with extra-adrenal adenocarcinoma (bronchogenic, thyroid, pancreatic, prostatic and thymic)
- B. Conn's syndrome of aldosterone overproduction due to neoplasia or bilateral hyperplasia—primary aldosteronism
- C. Secondary aldosteronism associated with edematous states and (?) malignant hypertension.
- D. Adrenal virilizing syndromes. Adrenal virilism of androgen overproduction (dehydroepiandrosterone or precursor) due to hyperplasia and neoplasia.
  - 1. Inborn errors in cortisol synthesis—congenital virilizing hyperplasia
  - 2. Incomplete penetrance of genetic defect in cortisol synthesis—adult virilizing hyperplasia.
- E. Mixed syndromes of corticosteroid and androgen overproduction due to hyperplasia and neoplasia
- F. Adrenocortical feminizing tumors

I. Adrenal Cortical Hypofunction

A. *Primary Adrenal Insufficiency* (Panhypocorticalism)

1. Acute—A provisional diagnosis of acute adrenocortical failure or Addisonian crisis requires that treatment be instituted without delay. Confirmation by a corticotropin response test should be postponed until recovery is obtained. The presence of pigmentation, hyponatremia, hyperkalemia and azotemia in a patient with peripheral circulatory failure is strongly suggestive of Addison's disease, however, the identical clinical picture may occur in salt-losing nephritis. Failure of the patient to conserve administered sodium while receiving adequate replacement of adrenal steroid hormones suggests a primary renal lesion. Peripheral vascular collapse due to septicemia has been attributed to secretory failure of the adrenals since the original reports of Waterhouse[11] and Friderichsen.[12] To date, permanent adrenal insufficiency has not been noted in those patients who have survived the Waterhouse-Friderichsen syndrome. Melby and Spink[13] have reported the concentrations of cortisol in the plasma of 22 patients with shock due to infection and all values were higher than basal levels measured in healthy subjects. In six patients tested, there was a rise in plasma cortisol following the administration of corticotropin. Finally, the therapeutic effects of administered cortisol in these cases cannot be regarded as due to "replacement" because doses of the steroid hormones "required" greatly exceeded the maximum secretory capacity

of the adrenal cortex. It is probable that acute adrenal insufficiency is not a feature of the Waterhouse-Friderichsen syndrome.

2. *Chronic Adrenocortical Insufficiency*—Addison's Disease. The frequency of diagnosis of Addison's Disease has increased. This increasing recognition is due in part to the availability of specific tests of adrenocortical function. In addition the entity of "partial" adrenal insufficiency has been recognized in which a remnant of functioning adrenal cortex is continuously stimulated by endogenous corticotropin to produce a normal basal steroid output. When an infusion of corticotropin is given, however, no rise in plasma cortisol can be detected. The patient with "incomplete" or "partial" Addison's Disease lacks adrenocortical reserve and symptoms are precipitated by trauma or febrile illness but may be absent or minimal without the superimposition of stress.

The diagnosis of adrenal insufficiency can be established reliably only by the demonstration of failure to increase blood cortisol levels or urinary 17-hydroxycorticosteroid (17-OHCS) or 17-ketogenic steroid (17-KGS) excretion in response to intravenous or intramuscular injections of corticotropin (ACTH). Urinary 17-ketosteroid (17-KS) excretion is unreliable as an index of adrenocortical functional capacity. A single determination of plasma cortisol, 24-hour urinary excretion of 17-OHCS or 17-KGS are not useful in the diagnosis of adrenal insufficiency and may be misleading. A test standardized by Jenkins et al[14] for urinary excretion of 17-OHCS is commonly employed:

Twenty-four-hour urine collections are made on two control days and two consecutive days during which 25 I.U. of ACTH is injected intravenously over eight hours. Normal subjects excreted 1-10 mg. 17-OHCS per day on control days and increased excretion to 5-25 mg. on the first day of ACTH stimulation and to 15-41 mg. on the second day. Patients with Addison's Disease fail to excrete additional 17-OHCS on days of ACTH stimulation.

Christy et al[15] simplified the testing of adrenocortical functional capacity by measuring the change in concentration of cortisol in the plasma before and after a four-hour intravenous infusion of ACTH. A similar procedure has been used by the author for the past four years:

An intravenous infusion of 25 U.S.P. units of ACTH (Upjohn, Sterile Corticotropin Injection) dissolved in 500 ml. of 5 per cent dextrose in saline is given over a period of four hours. Fifteen ml. heparinized blood is secured initially and at the conclusion of the infusion of ACTH. The erythrocytes are separated from the plasma within 30 minutes. The plasma samples are frozen until determinations of cortisol are made. A modification of the method of Silber and Porter[3] as described by Wu and Mason[16] is employed for analysis. The results for eight normal subjects are summarized in Table II. The mean control value for cortisol was 15 μg./100 ml. of plasma with a range of 5-24 μg. per cent. Following the infusion of corticotropin the concentrations rose to a range of 32 to 63 μg. per cent with a mean of 46 μg. per cent.

ACTH stimulation tests were carried out in nine patients with Addison's Disease. These results are summarized in Table III. It is apparent that no response to ACTH in any patient was obtained. This remarkable separation from the normal group has been observed repeatedly. Because of its high validity we have adopted this test as the *sine qua non* for the definitive diagnosis of adrenal insufficiency.

TABLE II. EFFECT OF ACTH (25 U.S.P. UNITS INTRAVENOUSLY OVER A FOUR HOUR PERIOD) ON PLASMA CORTISOL CONCENTRATIONS IN NORMAL SUBJECTS

B. *Secondary Adrenocortical Insufficiency* (Hypocorticalism)

It should be emphasized that aldosterone deficiency is not ordinarily observed in hypopituitarism. Some patients develop hyponatremia and its cause is incompletely understood. On the other hand, hyperkalemia is not observed. The pallor of panhypopituitarism differentiates it from the hyperpigmentation of Addison's Disease.

Patients having panhypopituitarism may have attenuated responses to stimulation by exogenous ACTH. There is often overlap with the normal control responses. The ACTH test will ordinarily separate primary from secondary adrenocortical insufficiency. However, in some patients with panhypopituitarism, no response may be detected on the initial ACTH test. Repeated stimulation of the adrenal cortex with zinc-corticotrophin (80 units IM daily for four days) restores normal responsiveness of the adrenal to intravenous ACTH. In Table IV the responses of nine patients with panhypopituitarism are tabulated. Investigations on the effect of bacterial pyrogen on pituitary-adrenal secretory activity[17] lead to the development of a new clinical procedure, the pyrogen test, for the assessment of ACTH production in patients following steroid therapy and in patients with hypopituitarism.[18] Blood samples for plasma cortisol determinations are obtained before and at 30, 60, 120, 180, and 240 minutes after an intravenous injection of Pyrexal Rx or Lipexal Rx*, a lipopolysaccharide (endotoxin) derived from *Salmonella abortus equi.* In healthy subjects, the injection of pyrogen is followed in two hours by an abrupt rise in plasma cortisol concentration. In patients with panhypopituitarism and patients receiving large doses of cortisol or its analogs, no response is obtained. Pituitary-adrenal responsiveness to injected pyrogen gradually improved up to five months after the discontinuance of hormone therapy.[19]

A chemical inhibitor of a specific adrenal enzyme (β-hydroxylase) has been developed from DDT-like cytotoxins. This substance is relatively non-toxic and has been designated as SU-4885. SU-4885 blocks the last step in the production of cortisol:

17-OH-progesterone → 11-deoxycortisol-[SU-4885] → cortisol. When cortisol activity decreases, the pituitary signalled by the mid-brain accelerates the production of ACTH. The ACTH, in turn, stimulates the production of more corticosteroid and the block by SU-4885 results in a pile up of 11-deoxycortisol (compound S) as a precursor. The 11-deoxycortisol gives a positive reaction to the Porter-Silber reagent and its increased levels indicates that pituitary function remains.[20]

II. Adrenocortical Hyperfunction

A. *Cushing's Syndrome of Cortisol Excess*

The diagnosis of Cushing's syndrome due to either hyperplasia or tumor of the adrenal cortex is confirmed only when urinary excretion of 17-OHCS (more than 12 mg./24 hours) is clearly elevated. The excretion of 17-KGS correspondingly reflect the excessive production of cortisol. Measurement of 17-KS excretion is not helpful in pure Cushing's syndrome. It should be emphasized that 17-OHCS excretion may fluctuate considerably, thus repeated urinary specimens should be examined if clinical findings warrant.[21]

*Kindly supplied through the courtesy of Dr. Fred Schultz of the Wander Company, Chicago, Illinois.

In those cases of Cushing's syndrome so studied, it has not been possible to demonstrate the normal diurnal variation of cortisol levels in the plasma. If, for example, the 8 a.m. level does not exceed the 8 p.m. level, the diagnosis of Cushing's syndrome is nearly certain.*

Hyperresponsiveness to ACTH in terms of blood cortisol levels and urinary 17-OHCS excretion is commonly present but not invariably. Further, the hyperresponsiveness to ACTH may be elicited in patients having tumors of the adrenal cortex and cannot be relied upon to distinguish hyperplasia from tumor.

Suppression of 17-OHCS excretion in urine to near zero levels can be accomplished in normal subjects with potent cortisol analogs (dexamethazone, fluoroprednisolone) in a dosage of 2.0 mg./day. Most patients with Cushing's syndrome continue to excrete excessive amounts of 17-OHCS in urine on this dose of the cortisol analog.

Doses of 8.0 mg. or more per day of these potent cortisol analogs will result in suppression of 17-OHCS output in urine in patients whose Cushing's syndrome is due to bilateral adrenocortical hyperplasia. This effect is not observed when the condition is due to tumor.

In summary, when elevated amounts of 17-OHCS are excreted in the urine in a patient having the clinical manifestations of Cushing's syndrome, the diagnosis is confirmed. It is generally agreed that no present test invariably differentiates between hyperplasia and tumor, although the suppression tests are most often correct. Most patients who have Cushing's syndrome must undergo surgical exploration of the adrenal glands, especially since the most reliable and definitive therapy (excision) can at the same time be accomplished. However, when hyperpigmentation is associated with the other features of Cushing's syndrome, an ACTH producing pituitary tumor should be ruled out.[22]

B. *Conn's Syndrome of Mineralocorticoid Excess—Primary Aldosteronism*

The constellation of muscular weakness, tetany, polyuria, polydypsia and paresthesias associated with hypertension in a non-edematous patient with laboratory findings of hypokalemia, alkalosis, hypernatremia, alkaline urine, isosthenuria and proteinuria is almost certainly due to the excessive production of aldosterone. The classical features of Conn's syndrome[23] are found in approximately one-fourth of the patients examined who are proved subsequently to have mineralocorticoid excess.

The diagnostic criteria for this "not-so-rare" disorder (perhaps 200 cases have been recognized since 1955) are inadequate. When renal insufficiency supervenes due to the hypertension, the biochemical findings become difficult to interpret.

The measurement of urinary aldosterone excretion is difficult and when carried out successfully may be unrewarding as the value may not be greatly elevated. The so-called "secondary" aldosteronism of nephrotic syndrome, cirrhosis with ascites, congestive heart failure and malignant hypertension is associated with much higher levels of aldosterone in the urine than are observed in cases of primary aldosteronism. The presence of hypokalemia in patients with malignant hypertension is not unusual so that the separation of primary from secondary aldosteronism may be difficult.

C. *Adrenal Virilizing Syndromes*

The excretion of increased amounts of 17-KS in urine by the female is almost always due to hyperplasia or tumor of the adrenal cortex. When 17-KS excretion is in excess of 50-60 mg., the presence of large amounts of dehydroepiandiosterone can be detected by a simple procedure, the Allen test.[24] When positive, the presence of an adrenocortical tumor is almost certain. However, tumor cannot be reliably differentiated from hyperplasia in all cases.

The presence of increased amounts of pregnanetriol in urine suggests a genetic disturbance, congenital virilizing hyperplasia. A simple comparison of 17-OHCS with 17-KGS (17-KGS would include pregnanetriol) is indicative of the adrenogenital syndrome in that the 17-OHCS may be normal or low while the 17-KGS are elevated. We have found this simple screening procedure very helpful.

Conclusions

1. Primary adrenocortical insufficiency is proved if ACTH infusions fail to increase the level of blood cortisol or excretion of urinary cortisol metabolites (17-OHCS and 17-KGS).

2. Secondary adrenocortical insufficiency is demonstrated by the failure of injected bacterial

*Observations of Dr. R. P. Doe and Dr. E. B. Flink.

pyrogen to increase blood cortisol levels in an individual responding normally to ACTH. Failure of urinary 17-OHCS to increase after 250 mg. of SU-4885 every 6 hours is also indicative of adrenocorticotropin deficiency.

3. Cushing's syndrome of cortisol excess may be confirmed by the presence of elevated 17-OHCS or 17-KGS excretion in urine.

4. Suppression tests using potent cortisol analogs may indicate the presence of an autonomously functioning tumor when doses of 8 mg. per day of dexamethasone fail to suppress 17-OHCS output. The converse relationship may not be reliable. ACTH stimulation tests are usually not helpful.

5. Conn's syndrome of mineralocorticoid excess is defined by the demonstration of inability to conserve potassium on a low K^+ intake and hyperaldosteronuria in a potassium depleted, hypertensive patient.

6. Virilism due to excess production of androgen by the adrenal cortex is usually associated with increased urinary 17-KS excretion. In congenital virlizing hyperplasia (adrenogenital syndrome), large amounts of pregnanetriol may be found. Low or normal 17-OHCS excretion coupled with increased 17-KGS excretion is highly suggestive of raised pregnanetriol levels in urine.

Acknowledgment

The author is deeply indebted to Drs. H. L. Mason, V. W. Mattox, and M. L. Lewbart of the Mayo Clinic, Dr. R. H. Silber of the Merck Institute for Therapeutic Research, and Dr. R. E. Peterson of the Cornell University Medical School for their advice and criticism on techniques of steroid analysis. He is also grateful to Drs. E. B. Flink and R. P. Doe of the University of Minnesota for their invaluable advice on clinical evaluation of states of adrenal dysfunction.

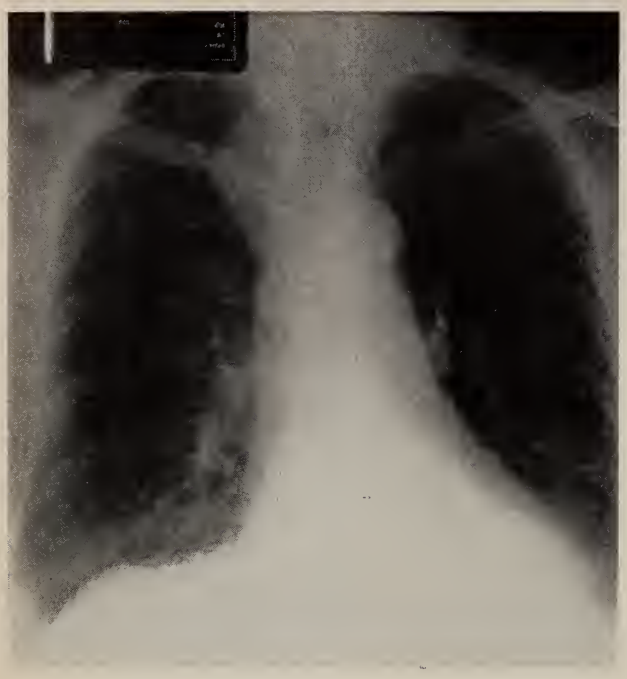

Fig. 1. A mass is present in the right superior mediastinum. The patient is an obese, hypertensive woman, aged sixty-eight, who had had a thyroidectomy in 1945. A twenty-four-hour radioiodine uptake was 30 per cent over the thyroid region in the neck with no uptake in the substernal or infraclavicular regions. Right thoracotomy (October 14, 1959) disclosed the mass to be an elongated and buckled innominate artery.

Buckling and Kinking

JOHN A. CULLIGAN, M.D.
Saint Paul, Minnesota

IT IS BECOMING apparent that a significant proportion of cerebrovascular thromboses have their origins in the extracranial carotid arterial system. DeBakey et al,[1] in reporting upon 174 patients with manifestations of arterial insufficiency of the cerebrum and upper extremities, found an extracranial source of arterial obstruction in 42 per cent. Direct surgical attack upon the carotid system in the neck has been utilized with increasing frequency since the procedure was first reported successful by Eastcott, Pickering and Rob[2] in 1954. Results following surgery have been gratifying in cases where neurologic deficits have been transient and arterial obstruction is found to be incomplete.[1,3,4] Those patients manifesting complete arterial obstruction coupled with persisting neurologic deficits derive much less benefit from arterial surgery,[3,5] though in a few instances brilliant results have followed operative intervention.[1,4] Appreciation of the importance of diagnosing intermittant insufficiency of the carotid arterial system before partial obstruction becomes complete and neuro-

Fig. 2. Forward intravenous angiocardiogram illustrating buckling of the innominate and right common carotid arteries. The patient is a hypertensive woman, aged seventy, with a pulsating globular mass in the base of the right side of the neck. X-ray examination ruled out an aneurysm.

logic changes irreversible has led to increased usage of carotid angiography. It is reasonable to expect that angiography will come to be even more commonly employed in persons with fresh strokes, the prodromata of impending carotid occlusion, or abnormal physical findings in the neck (See the papers by Millikan and Siekert,[6] and Hurwitz et al[7] for detailed descriptions of the carotid insufficiency syndrome). In view of this increasing interest in carotid angiography, a discussion of two abnormalities of the extracranial carotid system encountered from time to time is in order. These are "buckling" of the innominate-carotid artery at the base of the neck, and "kinking" of the internal carotid artery. Both terms have been employed loosely in the medical literature, sometimes interchangeably. Their delineation and differentiation is important, as their etiology, implication, therapy and prognosis differ.

Buckling of the Innominate-Carotid System

This condition, first described by Coulsons[8] in

1852, consists of a pronounced buckling of the innominate or carotid artery at the base of the right side of the neck. Occasionally, buckling is seen bilaterally, and rarer still, solely on the left. For the most part, it occurs in elderly, obese, hypertensive women with kyphosis.[9] It is thought to be an acquired process due to arteriosclerosis, with resultant elongation of the aorta, uncoiling of the aortic arch, and buckling of the proximal supra-aortic arterial branches. Buckling of the innominate or carotid artery is compatable with a normal life expectancy. The condition may be confused, however, with other lesions which require surgery.

If buckling is limited to the innominate artery, no cervical component is present, and a mass appears in the superior mediastinum (Fig. 1). If buckling of the innominate artery is overlooked, the mass may be thought to be of thyroidal, thymic, enterogenous or lymphatic origin, and an ill-advised thoracotomy may be undertaken.

If buckling involves both the innominate and the proximal carotid artery, a pulsating mass appears in the base of the neck, usually on the right. A mistaken diagnosis of aneurysm of the carotid artery may be made (Fig. 2). Also, the tortuous carotid artery often overlies the trachea in the suprasternal notch, and tracheostomy in such a person without prior palpation of the neck for pulsatile structures could end in disaster.

The diagnosis of buckling may be made if the possibility of its presence is kept in mind. Characteristically, the posteroanterior chest radiograph provides a clue in that the aortic arch rides higher than is usually seen, often presenting at or above the level of the clavicles.[16] We have used forward angiocardiography to good advantage in the delineation of the lesion. Fifty to 80 cc. of 90 per cent sodium diatrizoate Hypaque® or 85 per cent methylglucamine diatrizoate cardiografin is employed in conjunction with a Schönander rapid cassette changer. Single film technique is adequate if the circulation time from the basilic vein can first be determined with a tracer dose of radioactive albumin.

In summary, buckling of the great vessels at the base of the neck is a condition not requiring operation. Its significance is that it may be confused with lesions that do require surgery. If it is remembered that the process occurs in elderly, obese, hypertensive individuals who frequently are kyphotic, the diagnosis will seldom be missed.

Kinking of the Cervical Portion of the Internal Carotid Artery

This malformation has been reported sporadically in the literature since 1898. Such reports[12-15] have been directed chiefly to the otolaryngologist in connection with the occasional catastrophe of transection of the internal carotid artery during tonsillectomy, or rarer still, adenoidectomy. The anomaly consists of a tight sigmoid loop of the internal carotid artery beginning 2 to 3 cm. above the bifurcation of the common carotid artery. The loop most often lies in a sagittal plane, but occasionally is noted in a coronal plane. Very rarely the internal carotid artery may describe a circle.[17] Almost invariably the initial flexion of the artery is in a forward (anterior) direction. The descending limb is approximately 2 cm. long, and is followed by a second 180-degree angulation of the artery, from whence the vessel takes a rather direct course to the carotid canal in the base of the skull (Fig. 3).

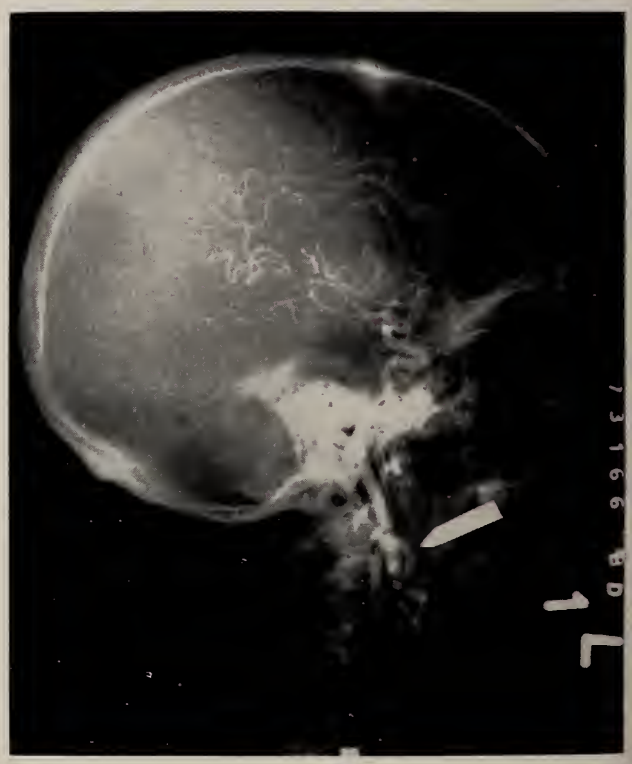

Fig. 3. Left carotid angiogram. (Courtesy of Michael P. Sperl, M.D., St. Paul, Minnesota.) The patient is a woman, aged fifty-three, who had had several episodes of transient (three to four minutes) right hemiparesis. The kinking of the internal carotid artery begins 3 to 4 cm. above the bifurcation of the common carotid artery.

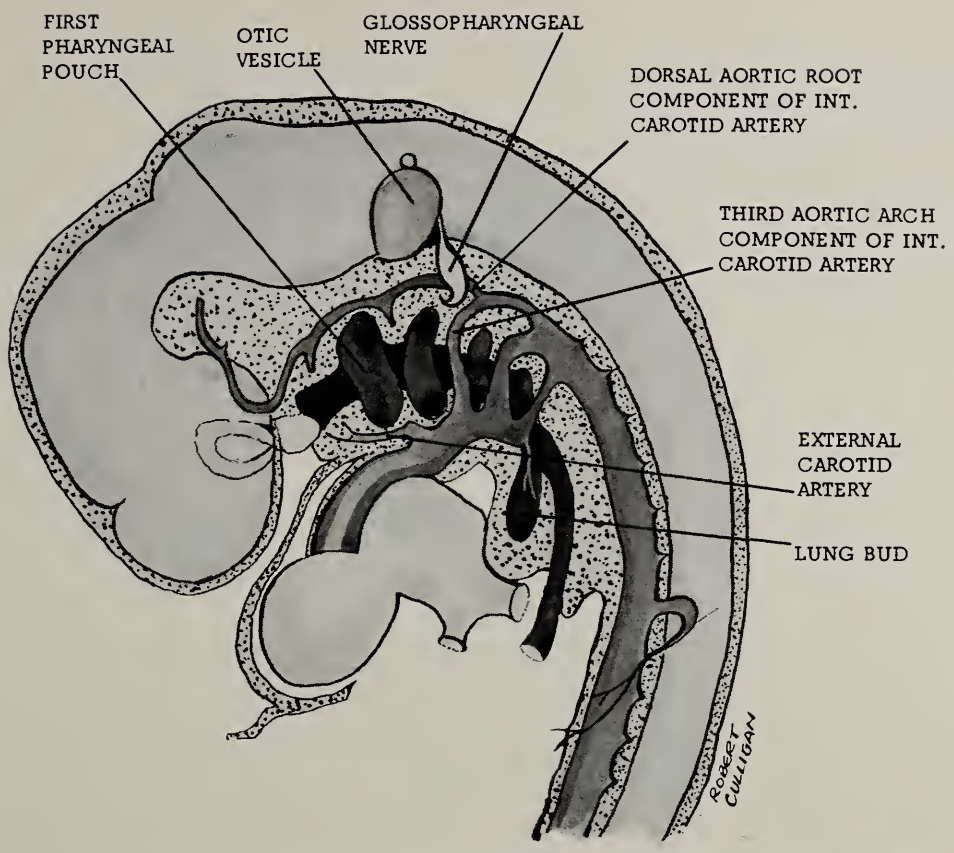

Fig. 4. 6 mm. human embryo. The first and second aortic arches have resorbed, leaving the third aortic arch, which together with the dorsal aortic root is to form the internal carotid artery. Note the pronounced anterior angulation of the artery at the junction of the third arch component and the dorsal aortic root component. Note also the intimate relation between the glossopharyngeal nerve and the angulation of the artery.

The abnormality has been variously attributed to arteriosclerosis, a regressive phenomenon, or an embryologic anomaly. The fact that the lesion has been observed in children as young as two years[18] makes the arteriosclerotic theory unlikely. Flemming[16] has attributed the phenomenon to a regression in the human being to the rete mirable (a cavernous type carotid artery) seen in a few species of ruminant animals. Few support this view. At the present time, most authorities favor the theory of embryologic derivation. This concept, introduced in 1898 by Kelly[11] and further elaborated by him in 1925,[20] is based on the observation that the internal carotid arteries are derived from both the third aortic arch and the dorsal aortic root. In the 6 mm. embryo (Fig. 4), note the pronounced anterior angulation in the vessel that is to become the internal carotid artery. Note also the intimate relation of the glossopharyngeal nerve (C. N. 1X) to the angulation of the artery. It is postulated that inordinate differential growth of the third arch portion of the internal carotid artery occurs as the heart descends into the mediastinum leading to persistance of the anterior angulation of the extracranial portion of the internal carotid artery, with the kink persisting into postnatal life. The theory is substantiated by the following:

1. The condition is bilateral in 50 per cent of cases, making one think in terms of a developmental lesion.

2. The initial flexion is forward, as is the angulation seen in fetal development.

3. The intimate association of the glossopharyngeal nerve and the arterial angulation in the embryo is invariably seen in the same relationship in the adult (Fig. 5).

Kinking of the internal carotid artery is of clinical significance in three ways:

1. The implications regarding tonsil and adenoid surgery are obvious, and need not be discussed, save to reiterate the maxim that digital and visual inspection of the pharynx for unusual arterial pulsation is mandatory before proceeding with either procedure.

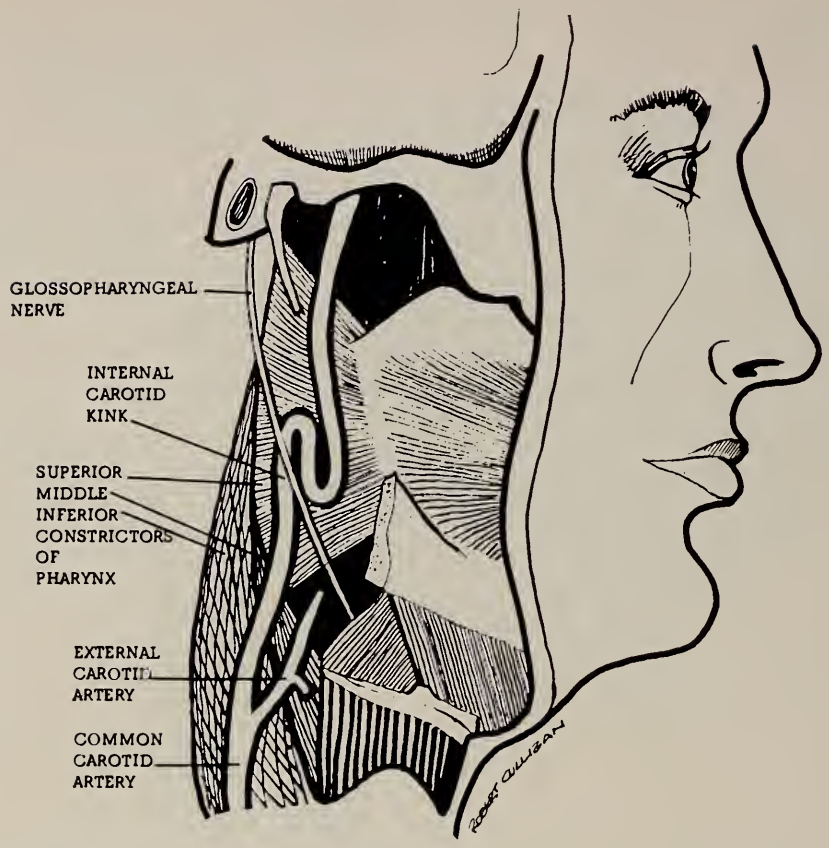

Fig. 5. Kinking of the internal carotid artery as it is most often seen. Note that the kink lies in close relation to the tonsillar fossa, being separated from it by superior constrictor of the pharynx. In addition, the intimate relation between the glossopharyngeal nerve and the kinked internal carotid artery is preserved.

2. Kinking may or may not impair the flow of blood through the carotid artery. Quattlebaum[21] has reported three cases of this condition manifesting the signs of carotid insufficiency. On the other hand, he has noted cases of kinking which are asymptomatic.

3. Acquired aneurysms are very occasionally encountered in association with kinking[22,23] (Fig. 6). These usually present as a pulsatile mass in the neck just below the angle of the jaw. Undoubtedly the aneurysm results from continued stress on the arterial wall at the angulation of the vessel.

Diagnosis of kinking of the internal carotid rests upon angiographic visualization of the carotid system. Although direct percutaneous carotid puncture is often employed, we believe that mapping of the entire carotid system is preferable. This may be accomplished by retrograde aortic catheterization by way of the femoral artery, or by direct puncture of the aortic arch via the right supraclavicular approach described by Eisman and Rainer.[24] In this way, both carotid arteries are visualized in their entirety, as well as the vertebral arteries, and proximal carotid or innominate occlusion (pulseless disease) will not be overlooked.

Indications for surgical intervention in this condition depend in part on whether the lesion is symptomatic. Quite obviously, aneurysms should be removed. Persons exhibiting neurologic manifestations due to carotid insufficiency should be explored before flow through the vessel ceases. It is our belief that those persons fortuitously diagnosed as having kinking who are asymptomatic should be followed expectantly, the repair being deferred until such a time that the lesion begins to cause difficulty.

Techniques for surgical correction of the lesion continue to evolve. Repair is best effected by excision of the kink and primary repair of the vessel. An alternative to excision of the kink is excision of a segment of the common carotid artery,[21] uncoiling of the internal carotid kink, and reanastomosis of the common carotid artery. We have had no experience with the latter method. Cross clamping of the carotid vessels is best avoided unless provision is made for internal or external shunting[1] during the period of occlusion.

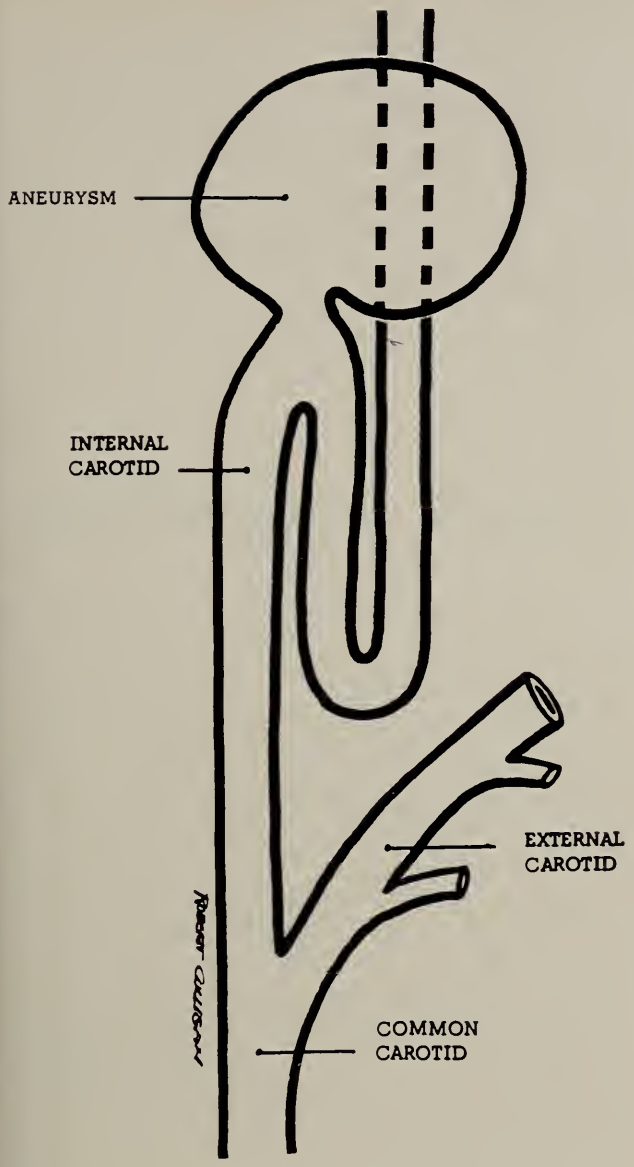

Fig. 6. An acquired aneurysm arising in a kinked internal carotid artery. Two months prior to being seen, this forty-year-old man developed a pulsating mass in the right side of the neck, just below the angle of the mandible. A thin-walled aneurysm was disclosed. The carotid artery was cross clamped without bypass or hypothermia, the aneurysm and the kink were excised, and primary arterial anastomosis effected. The distal carotid artery pulsated well and the patient made an uneventful recovery. At present, we would not cross clamp the carotid artery without either bypass or hypothermia.

Hypothermia[2] has been reported as an alternative to shunting during occlusion, but at present most authors favor the shunting maneuver.

In summary, buckling of the innominate-carotid arterial system and kinking of the internal carotid artery have been discussed. Differences in etiology, clinical implications, and therapy in the two conditions have been outlined and contrasted.

Brief Survey of the

Cholesterol Problem

With Clinical Applications

"To restrict fats or not to restrict fats: that is the question: whether 'tis nobler on the arteries to use corn oil instead of butter or to suffer the flush caused by nicotinic acid? Ay, there's the rub." Thus might a 1960 Shakespeare soliloquize. This article reviews the present status of the controversy raging about cholesterol and atherosclerosis, emphasizing that it is reasonable to attempt correction of an altered lipid mechanism when it can be done safely.

RICHARD W. P. ACHOR, M.D.
Rochester, Minnesota

WHEN questions concerning cholesterol and lipid metabolism are applied to the practice of clinical medicine a great many problems and much diversity of opinion become evident. At one end of this range of opinion is the belief that a disorder of lipid metabolism constitutes the major if not the entire answer regarding the cause of atherosclerosis. At the opposite pole is the arch-conservative opinion that lipid and cholesterol metabolism play only a minor role in atherosclerosis. My view belongs somewhere in the middle of these extremes, perhaps a bit nearer to the lipid hypothesis.

Read at the meeting of the Northern Minnesota Medical Association, Duluth, Minnesota, September 11, 1959.

From the Section of Medicine, Mayo Clinic and Mayo Foundation. The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

My brief survey will have four principal concerns: (1) a review of the evidence for believing that altered lipid metabolism is an important factor in the causation of atherosclerosis; (2) evaluation of the various blood tests associated with hypercholesteremia and atherosclerosis; (3) selection of patients for treatment; and (4) treatment of hypercholesteremia.

Altered Lipid Metabolism—A Prime Cause of Atherosclerosis?

Pathologic Anatomy.—More than a century ago, Virchow[1] recognized that atherosclerotic lesions have a fatty nature and introduced the concept that such lesions are a morphologic manifestation of a primary disorder of fat metabolism. Since

then it has been shown repeatedly that atherosclerotic lesions in the human contain large amounts of cholesterol and other lipid material, and that the proportions of these various lipid fractions closely parallel those concentrations present in human blood.[2-5] Radioisotope techniques provide data which indicate that ingested cholesterol finds its way into the atherosclerotic lesions of human aortas.[6]

Many workers now accept the belief that coronary sclerosis is not a necessary consequence of aging; and all of us have seen at necropsy smooth, widely patent coronary arteries and aortas from many elderly persons. Then, too, in some very young people atherosclerosis develops extensively; and nearly always in such instances severe hypercholesteremia is associated. In addition, pathologists frequently can demonstrate so-called healed atheromas in arteries of patients who have died of a prolonged wasting disease that was associated with normal or low concentrations of serum cholesterol. Hence in certain circumstances the atherosclerotic lesion appears to be suspectible of reversal or at least of arrest. This is a crucial point which challenges us to try to achieve this arrest or reversal by therapeutic means.

However, certain features of the morbid anatomy of atherosclerosis are not explained well by the lipid hypothesis alone. Commonly atherosclerosis is a patchy lesion, and in some cases only one or a few lesions are present in an artery that is otherwise normal. It is curious also that in the same patient certain arteries may be decidedly sclerotic and others entirely uninvolved. And again, may not hemodynamic influencing factors explain why branchings and curvings of arteries have a predilection for atheromatous deposit?[7] Certainly hypertension seems to favor the development of atherosclerosis.[8] These observations are but a few of the stumbling blocks in the path of the lipid hypothesis for atherogenesis.

Experimental Evidence.—Since Anitschow and Chalatow's work[9] with cholesterol-fed rabbits in 1913, animal experimentation has lent strong support to the lipid explanation of atherogenesis. Coronary and aortic atheromatosis has been produced experimentally in fowls, dogs, guinea pigs, rats, and monkeys. It may be noted that with regard to both histologic appearance and biochemical composition, the lesions seen in these animals are remarkably similar—although not identical—to those seen in human beings.[10] The important fact here is that almost all methods used in such experiments have one basic requirement in common: creation of a disturbance of lipid metabolism is necessary to produce the atheromatous lesions.[11] As a corollary to this finding it has been observed that all measures used to prevent or to ameliorate experimentally induced atheromatosis tend to restore lipid metabolism toward normal. A valid objection to data derived from animal experimentation is the obvious fact that disease in man offers a very different and more complex set of circumstances; hence results from animal work cannot be applied directly to the human, even though the inferences may be very suggestive.

Clinical Evidence.—Clinical studies may be cited to support the conclusion that atherosclerosis is related to disturbed lipid metabolism. Statistical studies have shown that mean concentrations of cholesterol in the blood are higher among patients with clinical coronary disease than among patients without such disease.[12] This difference is especially striking in younger age groups. The problem with such studies is that although they are valid in over-all consideration of large numbers of patients, they do not provide for reliable predictions from the cholesterol values of individuals.[13] It is well known that patients with diabetes mellitus, familial hypercholesteremia, xanthomatoses, and perhaps myxedema have a greater incidence of coronary disease than is present in a normal population of comparable age and sex. Again abnormal lipid metabolism with elevated values for blood cholesterol seems to be a common factor in these disease processes.

Correlations with sex status offer some evidence to support the notion that cholesterol is related to the development of atherosclerosis. The relative immunity of premenopausal women to coronary sclerosis is well known, and nearly always the various lipid concentrations in the blood of this group are less than for men of the same age. After the menopause, however, or following bilateral ovariectomy, the mean serum cholesterol and the incidence of coronary disease in the female rise concomitantly.[14] These observations suggest that the salutary influence of estrogen upon atherosclerosis is exercised through its effect on lipid metabolism, which is evidenced by normalization of cholesterol values.[15] Dock[16] recently has challenged this concept, however, and believes that environmental factors are more influential than the effect of estrogen *per se*.

It is widely recognized that a familial history of early death from coronary disease portends an unfavorable outlook for succeeding generations.[17] Thomas[18] has shown that three times as many young healthy medical students with hypercholesteremia had a parent affected by coronary atherosclerosis as did matched subjects with more normal values. Adlersberg[19] believed that an inherited disorder of lipid metabolism manifested by hypercholesteremia is a common factor among most young patients with coronary atherosclerosis. Again, the information seems true in the aggregate but is not specific for the individual.

Exercise has been advanced as a deterrent to atherogenesis. Good data to support this judgment are hard to come by, but some evidence is available. Morris[20] and his English colleagues have reported decreased incidence and severity of coronary disease among postal delivery men and conductors on buses as compared with the more sedentary postal clerks and drivers of buses. Mann and co-workers[21] have shown that exercise will prevent the rise in blood fats which otherwise occurs when normal subjects are overfed by intent.

Emotional stress has long been a favorite whipping boy to blame in part at least for the production of coronary disease; and the available data on it are extensive though not all consistent. Studies have been made of medical students whose concentrations of serum cholesterol increased during preparation for examinations and then returned to previous normal values when this period of stress had passed.[22] Similar changes were observed among tax accountants during and following the busy period of making income tax returns.[23] Russek[24] and Groom and associates[25] also have supplied studies to support the thesis that stress may favor the development of atherosclerosis. It is evident, however, that there can be no clear conclusion on this subject, for many uncontrolled and variable factors enter into consideration.

One of the most controversial subjects is that of dietary fat and its relation to atherogenesis. Much of the evidence regarding this comes from epidemiologic studies. Aschoff[26] noted a decreased incidence of atheromatous disease in Germany during the lean years of World War I and immediately thereafter. Similar observations have been made for World War II in Norway[27] and England. However, upon analysis of the English report[28] it was found that the coronary death rate began to fall even before fat rationing was instituted and started to increase again before rationing was abolished. Dr. Ancel Keys has supplied an enormous amount of information concerning diet and cholesterol concentrations of various population groups and their incidence of fatal coronary disease.[29] His interpretation stresses the fact that populations characterized by a low intake of dietary fat and by low values for serum cholesterol have not been found to have a high incidence of atherosclerosis or coronary heart disease. Keys has received ample supporting evidence from other investigators working with different racial groups and with similar races who have widely differing dietary habits.[30,31] Although this hypothesis is highly attractive it cannot be regarded as proved, since many factors may influence populations and their vital statistics. Such factors include type of dietary fat, amount of protein in the diet, total caloric intake, environmental surroundings, and various stress features. In addition the problems concerned with case selection, analysis of mortality records, and validity of diet studies work together against complete acceptance of this thesis.

For those who believe that blood coagulation and vascular thrombosis are important in the etiology of coronary disease, there is evidence to suggest that lipid metabolism has an important influence on these factors. Coagulation appears to be enhanced by alimentary lipemia and by increased concentrations of the various lipid fractions in the blood.[32] As yet, work in this field—especially the standardization and reproducibility of techniques for measuring coagulation—is not sufficient for firm conclusions.

From even this brief survey concerning the causation of atherosclerosis, I believe it is fair to say that altered lipid metabolism as manifested by elevated concentrations of cholesterol in the blood is a very important etiologic factor in atherogenesis, but that it is not the only one. Atherosclerosis is a complex result of many factors of varying influence. Despite the considerable lack of knowledge concerning atherogenesis, it seems worth while even now to do all we can to try to influence favorably a disease process of such supreme importance. Consequently, patients with hypercholesteremia should be considered for treatment designed to decrease the concentration of lipids in the blood, even though we do not yet have proof that such therapy has any beneficial effect upon the course of atherosclerosis.

Evaluation of Blood Tests for Abnormal Lipid Metabolism

Unfortunately the clinical recognition of early atherosclerosis is very difficult or impossible, and ordinarily must await some serious overt manifestation which is the result of arterial obstruction. By this time atherosclerosis usually is well established and may be in a stage which is irreversible. Because of these circumstances a wide variety of blood tests and indices have been advanced as means of detecting early or potential atherosclerosis. The physician now is confronted with numerous reports of evidence that this test or that index is the best guide to early recognition of the "atherosclerosis-prone patient." Such multiplicity of procedures implies that no one test is highly satisfactory.

The usual determinations of serum or plasma lipids which are available to the physician include: (1) total cholesterol; (2) phospholipids—and from these first two tests the cholesterol/phospholipid ratio is calculated; (3) fatty acids or triglycerides; (4) total blood lipids; (5) alpha and beta lipoprotein cholesterol—and their ratio can be obtained by paper electrophoresis; and (6) the "atherogenic index" as derived from analysis of serum lipoproteins by the ultracentrifugation technique developed by Gofman and his group[33] at the Donner Laboratories in California.

A great deal of study has been devoted to evaluating and comparing the merits of these various procedures. At the present time it seems a majority opinion that an accurate value for total serum or plasma cholesterol is as good or better an index of lipid metabolism as the results of other more complex tests.[34] In Mayo Clinic experience as well as in that of other investigators, it has been found that when significant changes occur in the concentration of serum cholesterol the other lipid values usually change in the same direction and in approximately the same degree. This is indeed fortunate, because determination of cholesterol is simpler and less expensive than are the other tests of lipid metabolism, and the service is more readily available in most parts of the country. In addition, more information involving more people over longer periods is known about blood cholesterol than about the findings from any other single test of lipid metabolism. If one must admit that even now the significance of an elevated cholesterol value for an individual patient is not certain, it follows that results from other, less widely studied tests will be even more equivocal.

The decision as to what constitutes normal values for cholesterol is usually dependent upon the specific technique and laboratory. In many laboratories a cholesterol concentration of 250 mg. per 100 ml. of serum is considered the upper limit of normal. This figure is derived from examination of many apparently healthy American adults. Almost surely this value is too high, for it can be assumed that some of these control adults had atherosclerosis or potential for developing the disease which was not yet evident. In addition, age and sex may cause important variations in "normal" values for serum cholesterol.[35] Even in the same individual there may be quite wide physiologic fluctuations during a period of observation without any obvious influencing factors being present. This variability and the eternal problem of laboratory error necessitate constant vigilance and astute discrimination by the physician in the interpretation of serum cholesterol values.[36]

Selection of Patients for Treatment

Thus far, two conclusions have been offered: first, that it is probably desirable to treat patients with abnormal lipid metabolism if this can be done conveniently and safely; and second, that the total blood cholesterol is regarded as the most practical of blood-test factors to assist in selecting patients for treatment and in assessing their progress. Now, how is the clinician to recognize these patients with hypercholesteremia? This really comes down to deciding which patients should have their blood cholesterol checked.

To begin with, an increasing number of patients request a cholesterol determination. Also, a number of patients are without symptoms but have regular examinations in which the physician includes the cholesterol determination routinely. Under either circumstance, positive findings are purely fortuitous.

A second group is composed of patients who have diseases or lesions which are commonly associated with elevated blood cholesterol values. (In this presentation vascular diseases are considered separately.) Persons with xanthelasma frequently have hypercholesteremia.[37] Cutaneous xanthoma nearly always indicates elevated concentrations of blood lipids, and the same is true concerning xanthomas of the tendons.[38] A prominent arcus senilis,

especially in younger persons, may offer a clue to hypercholesteremia.[38] Many patients with diabetes and myxedema have high concentrations of serum cholesterol. Occasionally upon examination of the ocular fundi lipemia retinalis is observed, and then invariably all blood lipids are found to be markedly elevated. Another means for identifying patients with hypercholesteremia is the examination of any turbid serum or plasma noted when the specimen is being used for some other test. Although lactescence of serum is not always accompanied by marked elevations in concentration of cholesterol. this occurs frequently enough to warrant full examination of all lipid components.

A third group who should be examined for hypercholesteremia might be termed "patients with vascular disease or potential vascular disease." This includes patients with overt coronary, cerebral, or peripheral atherosclerosis, particularly in the younger age ranges. Those persons who are asymptomatic but have a strong family history of vascular disease and death at early ages should have periodic determinations of blood cholesterol.

At the clinic, selection is made from these three groups on the basis of cholesterol values exceeding 250 mg./100 ml. of blood. Before treatment is initiated a second determination is made and perhaps a third, for it is important that the increased concentration of cholesterol not be a chance transient fluctuation or laboratory error. In assessing response to treatment, frequent determinations of cholesterol in the blood over prolonged periods are essential; and success is proved only by significant and sustained reduction. At the present time I do not attempt to lower further the cholesterol of patients whose values are within the normal range, even if they have overt atherosclerosis. A change in this decision awaits further knowledge concerning the etiology of atherogenesis. Again it must be stated clearly that present information does not afford definite proof that maintenance of normal or low concentrations of blood cholesterol prevents or mitigates atherosclerosis.

Treatment of Hypercholesteremia

In discussing treatment of hypercholesteremia I shall speak only of methods for securing and maintaining more normal concentrations of cholesterol in the patient's blood, and shall not include such therapy as may be indicated for the sequelae of atherosclerotic vascular disease.

Dietary Measures

Diets Low in Fat.—The first measure to consider is the oldest, simplest, and probably most physiologic—that is, diets which restrict fat intake. While new ideas have influenced thinking regarding low-fat diets, this form of therapy remains the cornerstone. If the patient with hypercholesteremia is obese, the obvious first measure is reduction of weight. A significant number of such patients achieve a good lowering of blood fats by merely attaining a proper weight, and some of these continue to have normal lipid values as long as they maintain the desired weight.[39] Unfortunately, others regain elevated cholesterol levels even though they remain at a desired weight. In these resistant patients and in those persons with elevated cholesterol who are not obese, the diet then must be restricted in fat content. Instead of the usual 40 per cent or more of the total caloric intake being supplied by fat, this amount must be reduced to 25 per cent or less.[40] Such a degree of fat restriction can be followed without extreme difficulty. and a number of patients show a satisfactory response to this therapy. For those who do not respond adequately, diets may be tried in which less than 15 per cent of the calories are furnished by fat. Such diets are very difficult to adhere to for long periods, especially if the patient is engaged in considerable physical labor. Then, too, such a program is not always successful even when it is strictly followed.

Spaced Fat Feeding.—For patients with familial hyperlipemia Wilkinson[41] has recommended that fat be excluded from the morning and noon meals but that the evening meal contain a normal quantity of it. The rationale is that with ingesting fat only once a day sufficient time will be furnished for adequate metabolism before a further increment of fat is added. This regimen is based on the thesis that some hyperlipemic patients can handle fats satisfactorily if given more time between periods of fat ingestion, and thus avoid a gradual build-up in concentration of lipids in the blood over a prolonged period. As yet, experience with this treatment is inadequate to permit definite conclusions; but it may offer a practical means of obtaining more normal levels of blood lipids in selected patients.

Unsaturated Fatty Acids.—This brings up the problem regarding types of fat in the diet. A considerable mass of data indicates that ingestion

of animal or dairy fats causes the elevation in blood lipids. These fats contain mostly saturated fatty acids which may have low iodine numbers. When such fats are restricted and the amount of fat from vegetable or some marine sources is increased, frequently a desirable lowering of elevated cholesterol ensues[42]. These "good fats" are rich in unsaturated fatty acids which contain the so-called "essential fatty acids" and tend to have high iodine numbers. Some workers believe that the ratio of saturated to unsaturated fatty acids is the important factor in determining whether the diet will be successful in decreasing elevated blood lipids. The greater the ratio of unsaturates to saturates, the better is the effect on lipids; a ratio of 3 or 4 to 1 seems quite effective.[43] At this time the precise action of unsaturated fatty acids is unknown.

What does this mean from a practical therapeutic standpoint? Experiences at the Mayo Clinic[44] as well as elsewhere[45] have shown that merely adding concentrated amounts of unsaturated fatty acids to the average American diet is not effective in lowering cholesterol. In addition, this regimen furnishes a large number of extra calories and makes it difficult to avoid gain of weight. Hence to be effective the amount of saturated fat in the diet must be restricted to approximately 20 per cent of total calories derived from fat. The remaining 80 per cent are derived from unsaturated fats. A number of cookbooks and diet lists now available offer excellent suggestions for regimens of this type. Although for success in lowering blood cholesterol it is necessary to adhere closely to specific diets that have rather marked restriction of animal and dairy fat, in practice many patients simply will not adhere to such diets for long periods.

Dietary Cholesterol.—Most opinion holds that in man the concentration of serum cholesterol is virtually unrelated to the intake of cholesterol in the diet[46] and that no rigid restriction is needed. Although this view may be accepted as a generalization there is some evidence to the contrary.[47] For the present, however, one need not be concerned about the actual amounts of cholesterol in the "low-fat diets" which have been suggested for diminishing blood lipids.

Exercise

It is probable that increase of physical effort causes a slight decrease of plasma cholesterol.[21] Hence a program of greater physical activity seems worth while in selected patients if not otherwise contraindicated. Exercise is not adequate as the only measure for lowering elevated concentrations of serum cholesterol, but seems useful when combined with other measures, especially restriction on total intake of saturated fats.[48]

Drug Therapy for Hypercholesteremia

Most physicians are acquainted with the difficulty in having patients adhere to diets which vary appreciably from those to which they have become accustomed. This pertains in great measure to diets which restrict fat, especially saturated fats derived from animal or dairy sources. In an effort to surmount this very considerable practical obstacle much investigation has been directed toward drug therapy of hypercholesteremia, and the search for safe, effective, and practical hypocholesteremic agents goes on apace; for it is well known that many patients will take medicines readily rather than diet. Although much has been achieved, the goal has not been attained as yet; and reports concerning such drugs are still to be considered investigational. Nevertheless, since interest in this endeavor is very great—extending even beyond the medical profession—it is desirable that all physicians be familiar with work that is being done.

Estrogens.—The use of estrogens to reduce elevated concentrations of blood lipids has been and is being studied intensively. There is little doubt that estrogens cause a moderate decrease of blood cholesterol in many patients,[49] and that the hormone protects against experimental atherosclerosis in animals.[50] As yet it has not been established that treatment with estrogens will influence favorably survival rates of patients having coronary atherosclerosis.[51]

Ordinarily, large doses of estrogens—from 0.2 to 2.0 mg. daily of ethinyl estradiol or its equivalent—are needed for a satisfactory hypocholesteremic response in men. These large amounts may not be necessary in postmenopausal women or in younger women with loss of ovarian function.[15] In men, therapy with estrogens has been limited by the production of gynecomastia, loss of libido, and testicular atrophy. In women, uterine bleeding may be a problem. These side effects have prompted considerable effort to develop an estrogenic substance which will lower blood cholesterol but have only minimal feminizing effects. Thus

far such an ideal compound has not been forthcoming, although some headway has been made.[52,53]

Thyroid.—Thyroid extract, thyroxine, and triiodothyronine have been used to lower concentrations of blood cholesterol in euthyroid patients.[51,54] Although some success has been achieved with these medications, large doses are required—from 4 to 6 grains daily of thyroid extract or its equivalent. Most workers have encountered evidence that such large doses may be dangerous for patients with overt or latent coronary-artery disease by increasing the degree of coronary insufficiency. In recognition of this hazard a considerable effort has been made to develop thyroid analogues which retain the hypocholesteremic effect but do not possess the calorigenic feature. At the present time this desired result has not been attained.[51,55] It is suggested that only modest doses of thyroid extract (½ to 2 grains daily) be employed for treatment of hypercholesteremia and that other measures be added as necessary to achieve a satisfactory therapeutic response.

Sitosterol.—Plant sterols, especially beta sitosterols, have been advocated for the treatment of hypercholesteremia. It is thought that these presumably inert sterols, which are structurally similar to cholesterol, compete with cholesterol for absorption in the gut. The resulting decrease in the amount of biliary and ingested cholesterol absorbed from the intestine lowers the concentration of cholesterol in the blood.[56] The drug, commercially available as cytellin, is taken as a liquid in amounts of about 1 ounce with each meal or intake of food. Most experience with sitosterol shows that it has a slight to moderate cholesterol-lowering effect with an occasional very good response.[44,57] However, some investigators have been unable to demonstrate any significant or sustained effect.[58] Sitosterol, although apparently harmless, is somewhat of a nuisance to take, has a chalky taste, and is expensive. It seems doubtful whether the modest lipid-lowering ability of sitosterol compensates for the disadvantages in its long-term use, but this agent may be helpful as an adjunct to other drug or diet therapy in resistant cases.

Nicotinic Acid.—The treatment of hypercholesteremia with large amounts of nicotinic acid has been studied with considerable interest since first reported in 1955.[59] The drug is given orally thrice daily after meals in doses varying from 0.5 to 2.0 gm. for a total of 1.5 to 6.0 gm. per day. Ordinarily no changes are made in the customary diet of the patients. This therapy has achieved significant, reproducible, sustained reductions in the concentration of cholesterol and other lipid components of the blood.[60,61] Also, a direct relationship between dose and effect is evident when the amount of nicotinic acid is increased or decreased. By use of adequate amounts of the drug, normal values for plasma cholesterol have been obtained and maintained in three fourths of Mayo Clinic patients in whom it was tried.[60] The mechanism by which nicotinic acid decreases levels of cholesterol in the blood is not yet known.

Side effects consist chiefly of cutaneous flushing and pruritus which are severe initially but usually subside within 10 days. Anorexia and nausea may be troublesome also. Occasionally abnormalities in tests of liver function and rarely a case of jaundice have been observed during therapy with nicotinic acid.[55,62] Impairment of glucose tolerance and increases in serum uric acid are seen in many patients receiving treatment.[55] These metabolic effects are not well understood; they call for more intensive study. Although nicotinic acid appears very effective and practical, this use of the drug must be considered an investigative procedure until its safety is definitely established.

Anticoagulants. — In addition to their anticoagulant effects, heparin and bishydroxycoumarin (dicumarol) have been used in patients with coronary disease and hyperlipemia because of their lipemia-clearing abilities. This therapy tends to eliminate the propensity for increased clotting which has been observed *in vivo* following alimentary lipemia.[32,63] However, there is no satisfactory evidence at present that these anticoagulants lower cholesterol appreciably over long periods or prevent the development of atherosclerosis. Hence their use for this purpose cannot be recommended except on an experimental basis.

Pyridoxine and Lecithin.—Data regarding the value of pyridoxine[64] and lecithin[65] in treatment of hypercholesteremic patients is too meager to evaluate at this time.

Lipotropic Agents.—Lipotropic substances such as choline, methionine, and inositol are mentioned only to reject them. There is no acceptable evidence that these drugs are effective in lowering levels of blood lipids or in the treatment or prevention of atherosclerosis.

Inhibitors of Cholesterol Biosynthesis.—Considerable recent investigation has been concerned with agents which interfere with the usual hepatic synthesis of cholesterol. This work is still experimental but preliminary reports are interesting. Certain vanadium compounds[66] appear to be effective in lowering cholesterol, as is a derivative of ethanol, triparanol (MER-29[67]). Much remains to be learned about these drugs but it is certain that this approach to the treatment of hypercholesteremia will be studied intensively.

Summary

A brief survey of the evidence linking disturbed lipid metabolism and atherosclerosis has been presented. Although much information is necessary to fill gaps in the etiology of atherogenesis, it is reasonable even now to attempt correction of altered lipid metabolism whenever this can be done safely. At present a number of therapeutic measures are available to the physician who wishes to accept the responsibility for treatment of patients with hypercholesteremia, and there is good reason to believe that even more effective treatment will be the reward of continuing research in the field of lipid metabolism and atherosclerosis.

Neuromuscular Syndrome

After Electrolyte Disturbance and Severe Acidosis

Treatment with the Artificial Kidney

JOSEPH M. EYSCHEN, M.D.
SATORU NAKAMOTO, M.D.
and WILLEM J. KOLFF, M.D.
Cleveland, Ohio

SEVERE and prolonged acidosis, associated with electrolyte disturbances, may produce a neuromuscular syndrome characterized by paralysis of the extremities, the diaphragm, and the intercostal muscles. The syndrome may persist after correction of the apparent chemical cause, evidently because neurocellular damage has been established. The possibility of neurocellular damage should make us strive for correction of acidosis rather than for supportive therapy only. Unfamiliarity with the neurologic syndrome may lead to useless neurosurgical exploration in order to rule out organic brain damage.

The following case reports illustrate the syndrome in patients with acidosis due to various causes: diabetic acidosis, uremia, and salicylate intoxication. Two patients were treated with the artificial kidney; the other was not.

Case Reports

Case 1. (Fig. 1).*—A woman, aged thirty-one, in diabetic acidosis and acute renal failure was referred to us. Five days prior to admission, she experienced backache in the lumbar area, dyspnea, and increased thirst. One day before admission, she was taken to another hospital in precoma diabeticum. The blood sugar was 590 mg. per 100 ml., and the HCO_3 content was 9 mEq. per liter. The urine contained albumin (3 plus), glucose, and acetone. She was given 3,000 units of crystalline insulin within twenty-one hours and was given fluids intravenously. The blood sugar decreased to 100 mg. per 100 ml. She became hypotensive and oliguric.

Upon admission to the Cleveland Clinic Hospital, the patient was hypotensive, had a rapid pulse, and was pale and lethargic. The findings on physical examination were otherwise normal. She did not have edema, and muscular strength was normal. She was in a state of acidosis: the serum HCO_3 concentration was 8.6 mEq. per liter (Fig. 1), and the pH of blood drawn from the femoral vein was 7.28. Neither sugar nor acetone was present in the urine at this time. The respirations were deep but not excessively rapid. Electrocardiographic changes were consistent with hypokalemia, and the serum potassium concentration was 2.8 mEq. per liter. She was treated conservatively with sodium lactate, potassium chloride, and insulin, and was given fluids as required. The next day the serum HCO_3 concentration was 14.2 mEq. per liter.

Four days later, although her blood sugar was controlled with insulin and there was no acetone in the urine, the acidosis was improving only slowly: the serum HCO_3-concentration was 18.4 mEq. per liter. Her blood urea concentration continued to rise to 158 mg. per 100 ml.; the serum potassium concentration was 3.0 mEq. per liter. Her urinary output increased. At that time we first noticed progressive weakness of the legs and also weakness of the facial muscles. On the fifth day of hospitalization at the Cleveland Clinic Hospital, she

Dr. Nakamoto is a special Fellow in the Department of Artificial Organs, Cleveland Clinic.

*This case was reported by R. R. Ozker; N. G. Richards, and O. P. Schumacher in the *Ohio State Medical Journal*, 55:1521-1522 (Nov.) 1959.

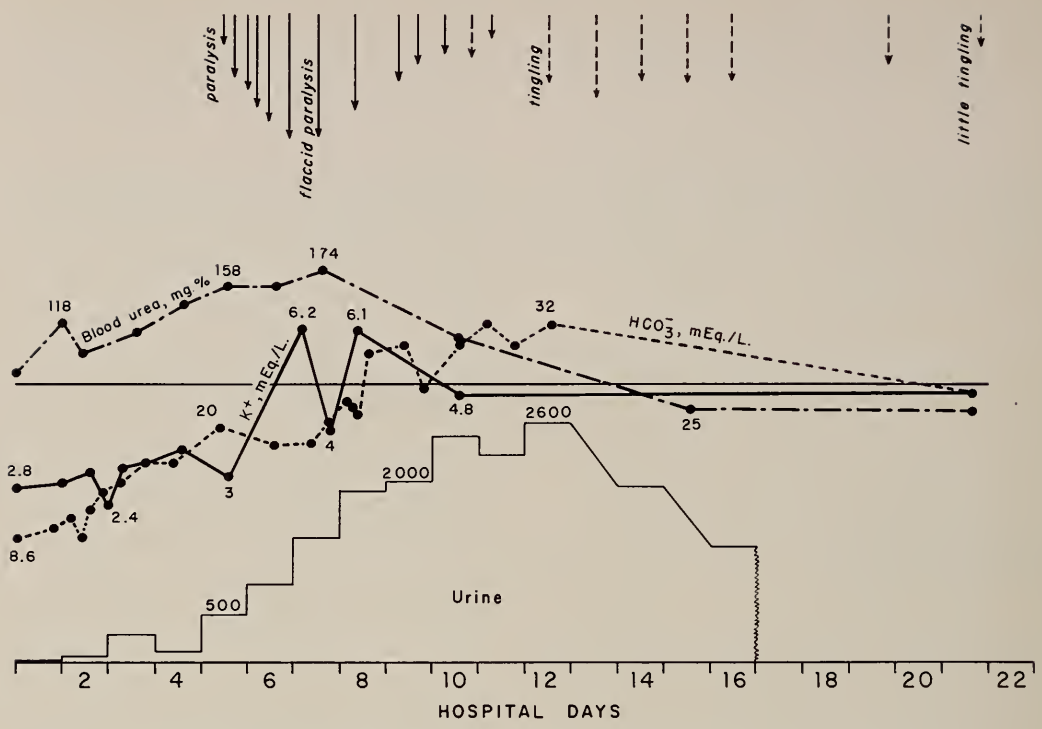

Fig. 1. A woman, aged thirty-one, with a diabetic coma presented a neuromuscular syndrome characterized by paralysis and tingling sensation of extremities. This syndrome persisted after a correction of electrolyte imbalance, especially of serum potassium.

presented extreme muscular weakness, predominantly in the proximal muscle groups, and more in the legs than in the shoulders. Diplopia was disclosed by a red lens test. Deep tendon reflexes were absent. Neither muscular tenderness nor fasciculations were present. Respirations were shallow and rapid and were performed with auxiliary muscles. Although it was not proved roentgenographically, diaphragmatic respiration did not seem to be effective. A respirator was kept ready for use nearby, but it was not needed.

On the sixth day, weakness of the sphincters of the bladder and rectum developed. On the seventh day, when the neuromuscular syndrome was most severe, laboratory studies disclosed: pH of the blood 7.4, serum HCO_3-concentration 22 mEq. per liter, blood urea 174 mg. per 100 ml.; the serum potassium varied between 4 and 6.2 mEq. per liter (Fig. 1). The fluctuations in the serum potassium concentration were caused by attempts to bring it under control by the administration of potassium and of potassium-binding resins. The blood sugar concentration was well under control, varying between 90 and 120 mg. per 100 ml. The cerebrospinal fluid was xanthochromic and the protein concentration was elevated to 280 mg. per 100 ml. An electromyogram showed changes consistent with fasciculations in the left deltoid muscle. The electromyograms of other muscles tested were normal. Tingling in the extremities began on the tenth day, but otherwise the neuromuscular syndrome slowly reversed.

On the twenty-sixth day the patient was discharged. There was still tingling of the fingers. The concentrations of serum electrolytes and of blood urea were normal, and the diabetes was well controlled.

Comment.—The neuromuscular syndrome appeared at the time that the acidosis was improving and it persisted after the concentrations of potassium and of other electrolytes were corrected. Acidosis was the most prominent abnormality found in laboratory studies, but the serum potassium concentration was also low (3 mEq. per liter during the paralysis, 2.4 before). The persistence of symptoms and the finding of excess protein in the cerebrospinal fluid indicate that the severe chemical disturbance may have led to neurocellular damage.

Case 2. (Fig. 2).—A Negro boy, aged fifteen, in renal failure with massive edema was referred to us. He lost 40 pounds in weight within a five-month period and backaches, weakness, and anorexia developed. Three weeks prior to admission, oliguria gradually set in and generalized edema developed. No history of sore throats or of other infections was reported.

Upon admission, the patient was lethargic; he had generalized weakness and flaccid paralysis of the arms and legs. His respirations were shallow. Severe generalized edema, oliguria, and ascites were present. The most significant laboratory findings were: serum HCO_3-concentration 10.4 mEq. per liter, serum potassium 8.6 mEq. per liter, blood urea 432 mg. per 100 ml., blood creatinine 22.2 mg. per 100 ml., and anemia. The blood sugar was normal: 85 mg. per 100 ml.

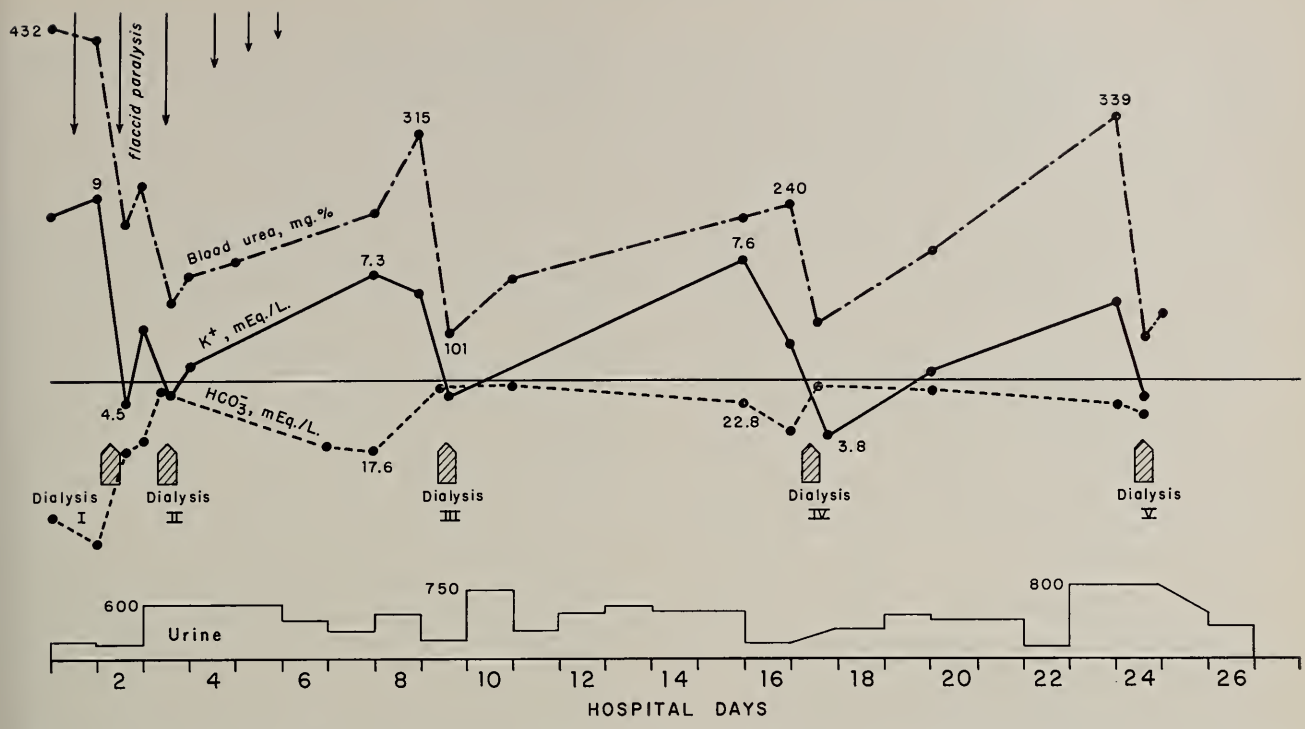

Fig. 2. A boy, aged fifteen, in a chronic renal failure developed severe uremia, metabolic acidosis and hyperpotassemia, and presented a neuromuscular syndrome. Repeated dialysis re-established his electrolyte balance, but the clinical improvement of neuromuscular syndrome lagged for days.

We treated this patient with the artificial kidney on two consecutive days, both for correction of the electrolyte concentrations and for withdrawal of body fluids by ultrafiltration. Simultaneously the anemia was corrected by the administration of whole blood, which can be done during ultrafiltration without the risk of overloading the circulation. The serum potassium concentration was reduced to 4:5 mEq. per liter. Two days later definite improvement in respiration and muscular strength was recorded.

After a third dialysis a renal biopsy was performed; chronic membranous glomerulopathy, severe fibrosis and destruction of the majority of the glomeruli, and tubular damage were found. His general condition could be well maintained by repeated dialyses with ultrafiltration. He was ambulatory, cheerful, and had a good appetite, but his renal disease did not improve nor did his urinary output increase to more than 500 ml. per twenty-four hours. He died at home one month after the fifth and last dialysis.

Comment.—This patient also presented the neuromuscular syndrome. The most prominent chemical abnormalities were uremia, acidosis, and potassium intoxication. Repeated dialyses and ultrafiltration re-established his chemical, water, and electrolyte balance, but the improvement of clinical manifestations of the neuromuscular syndrome lagged behind two days.

Case 3. (Fig. 3).—A little girl of twenty-five months was admitted to the Cleveland Clinic Hospital with salicylate intoxication. Four days prior to admission she fell down five steps, striking the right side of her forehead. She did not lose consciousness and no vomiting occurred; no bleeding from the ears or nose was noticed after the fall. Two days later a mild convulsion occurred. She was given an unknown amount of aspirin and later more aspirin, and became progressively sicker.

On admission, the patient was comatose, responded with motion to painful stimuli, and had severe Kussmaul's respiration. Respiratory muscles certainly were not paralyzed. The serum HCO_3-concentration was 5.4 mEq. per liter. The serum electrolyte concentrations were approximately normal. The blood sugar concentration was 197 mg. per 100 ml., blood urea 36 mg., and creatinine 2.2 mg. per 100 ml. The blood salicylate concentration was 35 mg. per 100 ml. Because it seemed that the child might die at any moment, dialysis was instituted promptly. There was immediate improvement of the Kussmaul's respiration and temporary improvement of her general condition. In spite of correction of the severe acidosis and removal of salicylate by the artificial kidney, she went into a deeper coma on the following day. Episodes of apnea and cyanosis necessitated assistance of respirations by positive pressure apparatus and later a tracheotomy.

Since the reason for the coma was not understood, pneumoencephalography and extensive neurologic and neurosurgical investigations were done. No space-occupying lesion was found. The cerebrospinal fluid contained 58 mg. of protein per 100 ml., 102 mEq. of

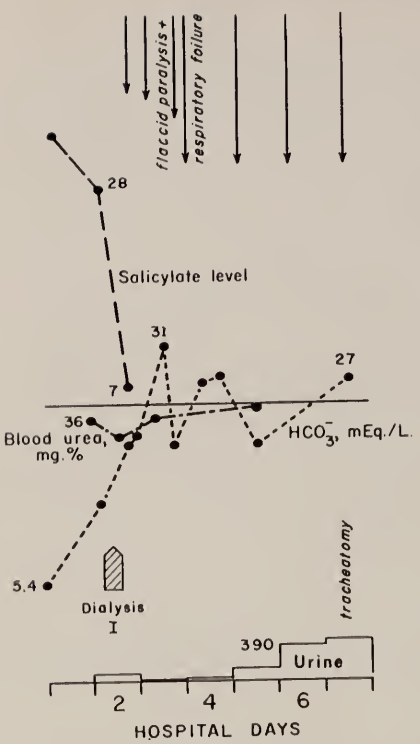

Fig. 3. A litle girl of twenty-five months with a salicylate intoxication developed severe acidosis accompanied by a neuromuscular syndrome. Despite a removal of salicylate and a correction of electrolytes by a dialysis, her condition progressed to an irreversible necrosis.

chloride per liter, and 600 red blood cells and 255 white blood cells per cubic millimeter; on culture it was found to be sterile. There was flaccid paralysis of the muscles of the body and of the extremities with respiratory failure, but her facial muscles and expression suggested that the upper part of the brain was intact. Laboratory studies at this time disclosed: pH of the blood 7.36, blood sugar concentration 75 mg. per 100 ml., and electrolytes, grossly normal. The serum potassium values varied between 3.1 and 5.4 mEq. per liter during these days.

The patient died fifteen days after admission because it was impossible to maintain sufficient pulmonary ventilation. The coroner's office reported: (1) salicylate intoxication; and (2) symmetric areas of subacute neurosis of the medulla and of the upper cervical spinal cord, notably at C1 and C2, and marked cerebral edema.

Comment.—In this case, a probably insignificant fall on the head led the original diagnosis astray. Serum potassium concentrations were within normal limits. The neuromuscular syndrome with flaccid paralysis followed severe acidosis caused by salicylate intoxication, while the serum potassium concentration was relatively little disturbed (3.1 mEq. per liter at its lowest). It seems that the initial damage progressed to an irreversible necrosis even after acidosis and the electrolyte disorder had been grossly corrected by dialysis.

Discussion

The neuromuscular syndromes seen in our patients were almost identical. The adult patients were lethargic and tired, but conscious and cooperative. They had diffuse muscular weakness, most often of the proximal muscle groups, as in myopathy. Deep tendon reflexes were absent. Weakness of the muscles of the face, pharynx, respiratory system, and trunk, such as may occur in polyneuritis, was observed.

It appeared that the upper part of the central nervous system was less affected than the lower part. In the child who died, degenerative changes were found in the medulla but not in the cerebral hemispheres.

The occurrence of similar muscular weakness has been reported in patients with potassium intoxication or depletion.[1,2] McArdle[3] believes that an abnormal potassium concentration in the blood serum is not so dangerous as rapid changes thereof. Others[4,5] think that changes in the proportion of intra- and extracellular potassium concentrations are determining factors to the occurrence of symptoms. Merrill[6] has pointed out that the cells can be depleted of potassium ion even when the concentration in the serum is normal or high.

In the patients described in this paper the neuromuscular syndrome did not regress promptly with correction of disturbances of the potassium ion concentration. The lowest serum potassium values were 2.8 and 3.1 mEq. per liter (Cases 1 and 3); the highest was 8.6 mEq. per liter (Case 2). In patients with simple "potassium" paralysis, we commonly find both lower and higher values.[7] Severe acidosis was the common denominator in the syndrome in the three patients described here, although disturbance of the potassium ion concentration may have played an intermediate role. The chemical disturbances had different causes: uremia, diabetic coma, and salicylate intoxication. A similar neuromuscular syndrome was seen in a fourth patient on the basis of diabetic acidosis. A fifth patient presented the same picture on the basis of infection and renal failure with acidosis. Since adequate treatment of the acidosis did not immediately reverse the symptoms, we believe that cellular damage was done which at best required

time for repair and in one instance (Case 2) was beyond repair. In a patient with severe diabetic acidosis, described elsewhere[8] (serum HCO_3 concentration 5 mEq. per liter), a week elapsed before coma and residual mental symptoms subsided. The neuromuscular syndrome may be overshadowed by the mental disturbance.

Similar clinical conditions may have been classified as diabetic neuritis or polyneuritis,[9] and indeed some neurotic symptoms were present, especially in case 1. As a matter of fact, Ozker, Richards, and Schumacher[10] described this patient, together with another one, under the diagnosis acute polyneuritis following severe diabetic acidosis. Mostly there were generalized muscular weakness, predominantly affecting the proximal muscle groups, and facial paralysis; but there were no disturbances of the sensory nerves except perhaps tingling of the finger tips in the recovery phase. Before the advent of the artificial kidney, patients in extreme uremia and acidosis may have shown the syndrome shortly before death, but if so it remained unnoticed or little attention was given to it.

The artificial kidney makes it possible to equilibrate rapidly body fluids and extracellular electrolytes to any desired level and to remove by dialysis nonprotein-bound toxic substances of such molecular size that they can pass through the dialyzing membrane.[11] Dialysis restores acid-base balance[12] not only by adding $NaHCO_3$ but also by eliminating the acids responsible for the acidosis.

If it is true that severe acidosis may lead to serious neurocellular and electrolyte disturbances, and sometimes to irreversible damage, it seems imperative to treat acidosis as vigorously as possible[8,13-15] and not to postpone dialysis until the damage is done.

Conclusion

It appears that there are risks involved when a patient is left for prolonged periods in a state of profound acidosis and electrolyte disturbance. Our aim should therefore be to correct these conditions. Dialysis eliminates the accumulated acids, whereas the administration of alkali only corrects the pH but leaves the organic acids in the organism.

Summary

A neuromuscular syndrome characterized by paralysis, mostly of proximal muscles, but sometimes including respiratory muscles, is described in three patients. The common denominator in the patient's chemical imbalance was severe acidosis, although elevated and subnormal serum potassium concentrations also occurred. The reasons for the acidosis and electrolyte disturbances were diabetic acidosis, uremia, and salicylate poisoning. The neuromuscular syndrome may become manifest while various clinical disturbances are being corrected, and neurocellular changes may proceed to an irreversible state after correction of the original condition. Awareness of the fact that the neuromuscular syndrome may be due to metabolic-chemical disturbances may obviate extensive neurosurgical diagnostic procedures, and lead to prompt correction of its cause by hemodialysis and ultrafiltration.

Dispensing Physicians and Clinic Pharmacies

A Challenge to Our Professions

HENRY M. MOEN, Reg. Ph.
Saint Paul, Minnesota

The following presentation by Mr. Moen does not necessarily represent the opinions of the Minnesota State Medical Association.

IN MINNESOTA, "inter-professional relations" is far more than a term vaguely denoting well-intentioned impulses but having little practical meaning. Here, the term describes a dynamic, productive inter-action which has been beneficial to all of the professions, agencies and institutions in the health field, and above all, to the citizens of the state.

In any community, medicine, public health, health education, dentistry, pharmacy, hospital administration—all combine to produce the overall pattern of health service. In Minnesota, these groups have worked together toward common goals, while at the same time clearly recognizing that each has a distinct and well-defined role in the total scheme of health services. Surely, this is one of the reasons that the people of this state enjoy what is perhaps the highest standard of public health in the nation.

The value of inter-professional relations has been well demonstrated by the long-standing alliance between Minnesota medicine and pharmacy. As an example, the two professions have for years been united in their opposition to promiscuous self-diagnosis and self-medication. The medical profession has repeatedly joined pharmacy in meeting attacks in the legislature and the courts which would have destroyed our pharmacy laws and legalized the unregulated sale of drugs and medicines in unlicensed outlets of all types. Organized pharmacy sponsored and supported the Durham-Humphrey Act which removed thousands of drugs from the "over-the-counter" category and restricted

Mr. Moen is Executive Secretary, Minnesota State Pharmaceutical Association.

them to sale by prescription only. The Minnesota Board of Pharmacy several years ago enacted regulations prohibiting the self-service sale of so-called "patent" drugs and medicines in Minnesota's drug stores. The Minnesota State Pharmaceutical Association has consistently carried on programs of education and public information warning of the dangers of self-dosing with non-prescription drugs and urging the public to seek early and thorough diagnosis and treatment.

Historically, Minnesota pharmacy has allied itself with medicine in the fight to preserve our traditional system of voluntary health care. At the present time, organized pharmacy is supporting by every means possible, the medical profession's opposition to the Forand bill and similar legislation.

At this time, the threats to our traditional pattern of voluntary health care and the freedom of the health professions are more numerous and graver than ever before. Now, more than ever, it seems essential that medicine and pharmacy, and, indeed, all of the health professions present a united front.

It would, therefore, be regrettable if a situation developed which might in any way weaken the bonds of loyalty and understanding that have linked medicine and pharmacy. Pharmacists and many physicians have recently felt concern over developments which could conceivably lead to such a situation.

I am referring to the dispensing of drugs by physicians and the establishment of pharmacies within medical clinics. The answer to whether or not these practices are desirable, must, of course, be decided by the medical profession.

As a spokesman for pharmacy, I merely wish to raise certain questions which I believe physicians will want to consider in arriving at the answer.

The physicians engaging in these enterprises give various reasons for doing so. One of the most common is the expressed desire to give their patients drugs at lower cost.

This explanation is presumably based on the assumption that (1) the price of drugs, as dispensed by the community pharmacy, is excessively high, and (2) the dispensing physician or clinic pharmacy can provide service and drugs of the same quality as the community pharmacist at a lower price.

The question of whether prescription prices are too high is a deeply involved and controversial one. However, here are some interesting figures which were recently published in the *AMA News:*

> "The nation's most extensive prescription price survey shows that more than 60 per cent of the prescriptions filled in twenty-three different sections of the country during a two-month period in 1959, were priced at $3.00 or less; more than one-third were priced at $2.00 or less; 8.6 per cent at more than $6.00 and 1.7 per cent at more than $10.00."

These figures and all of the other authoritative information available indicate that the percentage of prescriptions costing more than $3.00 is very small.

Not long ago, I had the pleasure of visiting with Dr. Austin Smith, president of the Pharmaceutical Manufacturers Association. Dr. Smith has been the chief spokesman for the drug industry at the Kefauver investigation of prescription prices.

Those who complain about drug prices, he said, can be divided into two groups: Those who don't want to pay and those who can't pay.

The first group, he went on, is made up of those individuals who object to paying for any type of health service—doctor bills and hospital bills, as well as drug bills. Even if it were possible to make a sharp reduction in drug prices, this group would continue to complain, he said.

The second group is made up of those individuals who are simply unable to pay for prescriptions or other medical services at any price—the medically indigent. The reduction of drug prices by half or three-quarters would do little or nothing to alleviate their plight. The solution to this problem, said Dr. Smith, is in the final analysis, a socio-economic problem which should appropriately be solved through the cooperative efforts of the health professions and the public welfare agencies.

Even if we were to assume that the dispensing physician does sell the same prescription drug for less than the pharmacist, can he appease the chronic complainer or help the person who simply cannot pay for drugs?

Over and above the cost of manufacturing and distributing a drug, there are two variable items which contribute to the price—manufacturer's mark-up and the pharmacist's retail mark-up.

Again, a remark made by Dr. Smith is very much to the point. If all the manufacturers' profits from prescription prices were wiped out, he observed, the problems presented by the low-income consumer and the chronically ill would remain. The saving to the consumer that would result

would barely be enough to pay for his daily newspaper.

It would, therefore, follow that even if the dispensing physician or the physician operating a pharmacy within a clinic were to sell drugs at cost, he would be doing little to help those who are actually in need of help.

What about the pharmacist's retail mark-up?

One answer to this question appeared in an article on prescription prices published in *Life* magazine. The article was decidedly unfriendly to the drug industry, it should be pointed out, and could in no way be interpreted as biased in favor of the pharmacist. Nevertheless, *Life* acknowledged that the average retail mark-up on prescriptions was scarcely adequate to meet the pharmacist's overhead. Further, the nationwide survey conducted each year by Eli Lilly Company shows that the pharmacist's profit from drug sales averages 5.7 per cent. Obviously, this represents a very small return on the pharmacist's investment.

In Minnesota, at least, even these figures seem over-generous. Years of daily contact with pharmacists throughout the state have convinced me that most prescription departments operate on a perilously narrow margin. In fact, if pharmacists were to charge against the prescription department all of the overhead expenses actually attributable to it, most of them would find that they are losing money in this vitally important section of the drug store.

Despite the widespread belief that prescription sales produce the major share of the pharmacist's profit, this department is only rarely self-supporting.

Pharmacists are frequently criticized for stocking a broad range of non-drug items. However, the revenue produced by this extraneous merchandise often helps support the prescription department. Without this form of "subsidization," it would be necessary to charge higher prices for drugs to maintain prescription service.

With these facts in mind, is it realistic to assume that the dispensing physician or the clinic pharmacy can provide the same quality of service, and more important, the same quality of drugs and medicines at a lower cost than the community pharmacist? Will they, like the community pharmacy, make available the great number and variety of pharmaceuticals which enable the physician to select from thousands of individual preparations the precise medication indicated?

It is sometimes argued that dispensing by physicians or the presence of a pharmacy in a clinic offers patients greater convenience in having prescriptions filled.

It is difficult to conceive a system that offers greater convenience to the public than the pattern of prescription service that now exists. There is a pharmacy within easy reach of virtually every individual in the state. Pharmacists in every community offer prescription service twenty-four hours a day—early in the morning until late at night, Saturdays, Sundays and holidays. Many pharmacists offer free delivery service and all are ready to respond to an emergency call at any hour.

For various reasons, many dispensing physicians and clinic pharmacists tend to favor lesser known drugs made by small, local manufacturers. Much has been said recently about the use of so-called generic equivalents in place of brand name preparations made by well-known, reputable manufacturers.

Those who advocate the use of generic equivalents argue that their use will reduce the price of prescriptions. This could conceivably lead to a system where the physician would be deprived of the right to specify the precise medication he wants his patient to have. In writing his prescription, the physician would be restricted to using a general descriptive term, without indicating the brand name or manufacturer.

Under our present system, the manufacturer stakes his reputation and future success on every unit of medication he markets. This is an assurance of quality, purity and efficacy, not to mention the fact that the well-established manufacturer has the extensive resources and technical equipment required to exercise rigid control over the drugs he produces.

The majority of patients seeking treatment want the most reliable and efficacious medication available, regardless of variations in cost. Physicians will be the first to say that their patients do not want cut-rate health. Physicians and pharmacists alike have heard requests for a "cheaper substitute" for a certain brand-name drug. But when actually faced with a choice between a brand-name and an unknown preparation, the patient will almost invariably prefer the former.

Perhaps the most serious indictment of the generic-equivalent system is the fact that it would interfere with the patient-physician relationship. Under this system, the responsibility for specifying

the brand the patient is to receive would be relegated to the pharmacist. In other words, the pharmacist, rather than the physician, would decide which brand the patient receives. I am sure that you, as doctors of medicine, are not willing to abdicate *this* responsibility. I am sure you want to exert maximum control over the management of your patients.

It goes without saying that both medicine and pharmacy have their public relations problems. In both cases, one of the major issues is *cost*—the so-called high cost of medical care and the so-called high cost of prescriptions. In fact, we know that these problems are serious enough to make government control a real and immediate threat to both professions.

The establishment of clinic affiliated pharmacies tends to aggravate the problem of medical care costs. Complaints of patients bear this out—patients visiting a dispensing physician or a clinic which houses a pharmacy will generally come to identify one with the other. When it comes to paying for medical care and for a prescription drug, does the patient make a distinction between the two charges? It is more likely that in the mind of the patient the cost of the prescription will be lumped together with the cost of medical care.

Even when the patient makes the mental distinction between the cost of drugs and the cost of medical care, it is quite possible the doctor will still be the main target of any resentful feelings. And I venture to say that many people will adopt this attitude, however, unjustified, without bothering to find out whether the physician has any financial interest in the pharmacy. In fact, the same attitude can be expected to develop even when the pharmacy is wholly owned by the pharmacist in a clinic building. The mere presence of the pharmacy in the clinic will tend to identify it in people's minds as *part* of the clinic.

The operation of a clinic pharmacy would perhaps aggravate the problem by seeming to add a significant sum to what patients regard as their "doctor bill."

Is it not also likely that the dispensing physician and the clinic affiliated pharmacy will tend to restrict the patient's choice? Free choice of physician is, of course, a traditional right, which is to be vigilantly guarded and preserved. Free choice of pharmacist is also a traditional part of our pattern of health service. The dispensing physician and the clinic pharmacy do not, of course, literally deprive the patient of free choice. But in actual practice, it seems highly probable that the availability of drugs in the doctor's office or the clinic pharmacy will create a psychological situation where the patient will almost feel compelled to purchase prescriptions there.

There is another point which should be considered, since we are examining all aspects of this question. Both pharmacists and physicians are aware of the persistent and unpleasant charge that doctors and pharmacists enter into compacts for the purpose of exploiting patients. These vicious, baseless accusations insinuate that physicians prescribe unnecessarily or prescribe excessively expensive drugs to take advantage of a "kick-back" arrangement with the pharmacist.

Such charges impung the integrity of the pharmacist as well as that of the physician. Nevertheless, we must recognize the fact that such suspicions, however groundless, exist in the minds of some of the public. Therefore, it seems altogether possible that the clinic affiliated pharmacy may create a psychological atmosphere which will foster and perpetuate these suspicions. The mere physical proximity of the pharmacy and the clinic could, indeed, arouse suspicions where none existed before. And while completely unfounded, this factor could again serve to aggravate a problem which is already serious.

Over the years, there has been a trend for the physician to disencumber himself of the many tasks which do not require his specialized skill and knowledge. He has shown an increasing desire to delegate responsibility to supporting specialists—x-ray technicians, anesthetists, biologists, pharmaceutical manufacturers and pharmacists. In doing so, he has been able to serve more patients more effectively, thus helping to meet the unprecedented demand for medical care, despite the shortage of physicians.

In these remarks the following questions have been presented: Does the dispensing physician or clinic-affiliated pharmacy answer a need within our established scheme of health services? Will they offer the same quality of drugs and medications to patients at a lower price? Do they answer a need for more convenient availability of drugs?

Among the majority of Minnesota's doctors of medicine, I know the answers to these questions will be determined by what is best for the medical profession generally and for the health and welfare of the people of Minnesota.

Medicine and Its Practitioners in Mower County Prior to 1900

NORA H. GUTHREY
Stewartville, Minnesota

Dr. O. H. Hegge, of Austin, has spoken of the generations, in chronology not kinship, of physicians in Mower County, mentioning some of the earlier men who had survived into his day, and including men who now are in practice. He places Dr. Orlenzer Allen and Dr. John N. Wheat, of Austin, and their immediate contemporaries, as well as Dr. W. F. Cobb, of Lyle, Dr. G. W. Gray, of Brownsdale, and Dr. W. H. McKenna, Dr. W. L. Hollister, Dr. O. W. Gibson, all of Austin, in the first generation. Dr. Hegge and his brother Dr. C. A. Hegge, who came to Austin together in 1893, Dr. F. E. Daigneau, Dr. A. W. Allen, and others in their approximate age group, were of the second generation, and those who entered practice after the turn of the century, and in later decades, were, and are, of the third and the fourth generations, "as the first 100 years of medicine in Mower County are coming to a close." Each generation of physicians feels superior in resources to the preceding generation, and the physicians of today, middle-aged and younger, not to mention recent graduates, wonder how the "old-timers" got along without the benefits of modern science. In 1911 Dr. Arthur West Allen, son of the first physician in Austin, and himself a "pioneer doctor" (in practice 1885-1940) by present-day standards, wrote as follows:

> The early history of the pioneer physician is naturally a story of feeble resources. His professional limitations were, therefore, necessarily great. To enable us to understand these limitations we must take a retrospective glance at the conditions of medicine sixty years ago. Imagine, if you can, the forlorn condition of the doctor without our present means of physical diagnosis, without the clinical thermometer, the various specula, the rhinoscope, the aspirator, and many other similar instruments; without the aid of hematology, of anaesthetics, of antisepsis, of the modern microscope, without our laboratories and experiments, our chemistry, our bacteriology, our roentgen rays, our experimental pharmacology, and our antitoxins—without anything except his eyes, his ears, his fingers, his native vigor and resourcefulness; then we can appreciate the professional limitation of our fathers, appreciate no less the triumphal march of medicine during a single lifetime. It requires no prophet's power to foretell the fact that the science of medicine stands at the hour upon the threshold of an era which will belittle all the past. In this most wonderful era of the world's history, the magic age, the science of medicine is rapidly being elevated into the position of one of the bulwarks of society and one of the mainstays of civilization.

To Dr. Allen's viewpoint his successors of today may add their own wonder, seventy-two years since he began practice, "How did his generation do without antibiotic drugs such as penicillin and the many others that have been developed in recent years, or blood transfusions, or glandular hormones such as cortisone? Physicians still feel that they are upon the "threshold of an era" in scientific medical progress, and can but wonder what the historian of 2001 will think of them and their "meager facilities."

While his professional life was rugged enough, the early physician's family life was certainly no less filled with hardship than that of his contemporaries in other occupations. Diphtheria was the dread disease of those times, and parents then must have feared its fatal effects, much as parents now fear the crippling disease, poliomyelitis. In the Hollister family scrapbook there is a newspaper clipping, undated but probably about 1878, which describes the tragic deaths from diphtheria of two little sons of Dr. O. W. Gibson, and two children of his next door neighbor H. A. Fairbanks. Each family had three children, each lost two of them. When Dr. Hollister died in 1921, his obituary, like so many of that day, contained the terse and unrevealing sentence, "Two children died in their infancy." The family scrapbook, however, contains newspaper accounts of the death of one son, about twelve years old, in 1878 from diphtheria, and of another, aged twelve years, in 1882, from lockjaw following a hunting accident. From such experiences in their own homes, it is understandable that the physicians developed the sympathetic understanding of and concern for their patients for which they are remembered.

The first physician in Austin undoubtedly lived in a log cabin. In the *History of Mower County* published in 1911 is found a delightful description of the cabin of "Judge (In Embyro) A. and Wife." This no doubt was the first home of Ormanzo Allen, twin brother of Dr. Orlenzer Allen, the pair being the first professional men to settle here (1856), when "about a dozen families were scattered here and there in the 'openings.'" The cabin, typical of all the earliest homes, better than some, had one window, which shoved sidewise to open, the door was hung on wooden hinges, and the ceiling barely cleared the heads of the occupants. Stools were made of boxes, and a bed, of prairie grass, was on the floor. This shelter was in sharp contrast to the handsome residence of Judge Ormanzo Allen that is pictured in an illustrated historical atlas of 1874.

As mentioned earlier, Dr. John N. Wheat came to Austin only a few months later than Dr. Orlenzer Allen, "yet early enough so that Mrs. Wheat gave birth to the first female child, Carrie M. Wheat, born in the new settlement." The first male child (Austin, son of George Bemis) had been born a year earlier, B. D. (before doctors). Dr. Wheat must have hoped to give his daughter every advantage, since he is credited with having purchased the first piano owned in the city. At an early settlers' reunion, in 1876, Dr. Wheat described one of his experiences in the winter of 1866, "when the snow was four feet deep on the level, and drifted badly in places, and at times so crusted over with ice that a man could walk upon it without much difficulty, only breaking through occasionally." Over or through this depth of snow he was called professionally to attend a patient in the Vanderwalker neighborhood, a settlement some six miles northwest of Austin. Here he found twenty-three persons—men, women and children—inhabiting one log house, its single room 14 ft. by 16 ft., without floor or windows, unless the two small panes of glass framed in the logs might be called windows; with stools for chairs; prairie grass for beds, and without bread or vegetables for food. Here were three persons dangerously sick, and in order to give them proper attention he found it necessary to make the journey every other day on foot in great discouragement, often breaking through the snow crust and sinking to the waist. Experiences of this type, altering name, date and place, were known to every pioneer physician of the early era.

Public Health and Public Welfare

The Minnesota Code of 1851 authorized justices of the peace, village trustees and city councils to exercise the functions of relief and maintenance, always by local agents, to those among the sick poor who did not receive due care from relatives.

Soon were added the duties of abating nuisances injurious to health and comfort, and next of imposing quarantine against smallpox and other contagious diseases. The General Statutes of 1866 made town supervisors local boards of health. In 1872, owing largely to the initiative of Dr. Charles N. Hewitt of Red Wing, the Minnesota State Legislature officially recognized health as a matter of public concern and established the state board of health, to act for the prevention of disease and the promotion of general health. The powers of the state board of health were comprehensive but merely advisory, extending into counties and townships. In 1873, the authority of the state board was strengthened to the extent of requiring each township to elect a town board of health of not less than three members, one of whom was to be a physician.

In accordance with the state law passed in 1869, the official records of births and deaths began. This ruling proved extremely difficult to enforce, even after fines were imposed on those who ignored it. As late as the nineties, the state board of health was continuing its efforts to educate the public in the importance of observing the law.

In the pioneer years living conditions were necessarily crude, and measures for sanitation were primitive or, in some localities, lacking. The early physicians met the problems of public nuisance, endemic disease and epidemic disease as well as they could, but their knowledge and experience were inadequate, and the laity were largely uninformed or indifferent, many of them ignorant and superstitious.

Armstrong commented, in some unpublished work on early conditions of medical practice in Mower County, that in this county there were fewer medical impostors than in counties to the east, fewer crimes, that there was lower incidence of contagious diseases in general and that, notably, Asiatic cholera was not known here. He inferred that there was less, or later, opposition in Mower County than elsewhere in southeastern Minnesota to quackery, crime, and inebriation, and less awareness of the danger of contagious disease. The public was slow to recognize the necessity for local boards of health. Local and county medical socities (q.v.) were not organized until a relatively late date.

The Poor, the County Coroner, and Boards of Health

In some counties *the poor* were attended by local physicians who sent in their bills, at the end of the year, to the county commissioners. The first such record in Mower County is of bills presented in 1859 by Dr. Orlenzer Allen and Dr. H. L. Coon for attendance on the sick poor. Mower County had not long been settled when it became necessary to establish a county poor farm, which was placed at Le Roy from 1868 to 1876; in the latter year it was established in Lansing Township, near Austin.

In Mower County, beginning in the eighteen seventies, two county physicians usually were appointed by the year, the salaries running from about $60 or less to $150 annually (the physicians furnishing medicines and their own transportation). Occasionally, other unofficial physicians, also presented bills for service to the poor. The county was divided, primarily because of topography, and secondarily by political tension (as mentioned earlier) into the West Half and the East Half, in point of service by the county physicians. In the early years Drs. J. N. Wheat, R. A. Barnes, W. L. Hollister, C. B. Thrall and G. M. Allsdurff were among those who served as county physicians.

Although some of the neighboring counties revised their rulings for the care of the poor, Mower County, in the eighties, continued to elect regular county physicians as it had done in previous years. Drs. L. D. Jackson, O. W. Gibson, G. W. Gray, W. A. Frazer, A. MacDonald and C. H. Johnson were some of those who served as

county physicians in this period and later. In fact, over a long period, most of the practicing physicians of the county served at one time or another in this capacity. A few of those who held the office in the nineties were Drs. C. A. Hegge and O. H. Hegge, Fanny G. K. Fiester and H. F. Peirson. In the latter period three or four physicians were elected each year, at the nominal salaries mentioned heretofore, the amount annually depending on the size of the district served.

The *county coroner,* in all counties, was one of the first officers needed. In many counties, for some years, the coroner was a layman. In Mower County the coroner was elected each year, and a physician regularly served in that office. Dr. Orlenzer Allen was coroner in Mower County in 1856, the first physician to hold the office, and in 1859 and later. Payment of the coroner depended on the amount of service he was called on to perform. Many different physicians served from time to time, as will be mentioned in the respective biographical sketches. Dr. R. A. Barnes, in the sixties and seventies, was coroner for many years. Much later, Dr. A. E. Henslin, who came to Le Roy in 1895, was coroner for twenty years.

Some time during the eighties, Austin formed a *board of health,* as did Grand Meadow, and subsequently other villages followed suit. The physician who was appointed city or village health officer was responsible for sanitation and for quarantine, but possessed little real power or authority. When members of the board served as physicians, they usually drew small salaries. In general, the early boards of health in the county ordered the citizens to clean up alleys, streets and premises. They analyzed well water, and reminded the population of the rules concerning contagious diseases. Some of the residents were obstructive, and some were cooperative, to the extent of sending to the local newspapers pungent comments on the delinquencies of others in such matters as wells, alleys, cellars and outbuildings. The boards reminded the citizens of the necessity also of registering births and deaths.

Diseases and Epidemics

Definite information about epidemics and disease in Mower County, in the sixties, particularly, is relatively scarce.

Diphtheria.—Mention has been noted of severe outbreaks of diphtheria in 1864, 1866, 1867, 1870 and later. There were sporadic cases of the disease almost every year. In Le Roy, in 1864, the newly arrived Dr. G. M. Allsdurff gave valiant service during an epidemic. In 1866 Dr. J. L. Martin, of Frankford, combated a severe outbreak of diphtheria in the community. In 1870 Dr. E. J. Kingsbury, who had just then returned to the county, to Le Roy, after ten years in Fillmore County, gave outstanding service in another epidemic. Diphtheria again was epidemic in the locality of Le Roy and elsewhere in the winter of 1878, and in the first three months of 1879 many persons were ill from it. In that period there were several deaths among the children of physicians.

During the eighties diphtheria prevailed to a much greater extent than in previous years. In fact, judging by newspaper references, there was only one year in that decade in which the county seems to have been free from the disease. It was most prevalent during the winter months, owing perhaps to the closer association of persons indoors during the colder weather than in the more open seasons, and to the greater opportunities for contagion among children during sessions of school. The disease was spread throughout the county, and the schools were closed because of it. Its virulence is proved by the numbers of deaths recorded. As if to make up for the high death rate, among children, one observer noted, it was usual to find a correspondingly high birth rate, both among families in the lower financial brackets and among families who could maintain a higher standard of living.

In almost every year during the nineties, diphtheria was present somewhere in Mower County and the adjoining counties. In the last half of the decade schools commonly were closed part of the time, and public meetings were barred. At that period antitoxin was just beginning to come into general use.

Other Diseases.—In the winter of 1868-1869 and into the early spring, measles in an extremely severe form afflicted neighboring Freeborn County and to some extent Mower County. There were few fatalities, but in the affected communities hardly a family escaped the disease.

Measles, chickenpox, "throat trouble," fevers, ague, meningitis and erysipelas were each represented prior to 1900. Whether the following proves the general healthfulness of the region or whether it is an indication of the opposite, is doubtful: At any rate, one of the respectable physicians of Austin included on his professional card, in 1872, the information that he gave special attention to embalming, deodorizing and disinfecting dead bodies.

Whooping cough, particularly in 1886, was troublesome. From time to time cases of typhoid fever appeared, and "typhoid malaria," but these occurred only in the country or in the small villages, and very few persons were affected.

During the first few years of the eighteen seventies scarlet fever often was present. In July, 1870, there were reports of its appearance around Austin. In February, 1871, many cases were reported in the city, and at about the same time the disease appeared near-by in Freeborn County. Outbreaks continued into June 1872. In January, 1873, the disease again was reported in Austin, and in April in Freeborn County. It prevailed again to a considerable extent in 1880, 1881, 1884 and 1885. In 1886 "Austin was busy using sulphur." In 1889 there again were a few cases.

The only mention found of smallpox in the newspapers in the eighteen seventies concerned two families in Freeborn County in 1872. If these were the only cases locally, Mower and Freeborn Counties were fortunate, for the disease was prevalent in other parts of the state. Only one case was reported in Mower County in 1882.

As for malaria, the following statement was published in 1883: "Our situation is necessarily healthful and free from malaria. Our elevation is an effectual and perpetual injunction against the inroads of fevers of any kind."

Although the number of sufferers from pulmonary tuberculosis was not greater in Mower County than in any other section of the state, the presence of these invalids was a worry. The early advertisements of the colonizing companies, that the salubrious climate of Minnesota was a cure for "consumption," had long since been discontinued. Many types of medical treatment were advocated. Among the newer ones which came into vogue was "medicated inhalation." This was used for all pulmonary troubles and especially for tuberculosis. A physician who used the treatment was regarded as progressive. The popularity of the method became evident when the local tinsmiths began inventing and trying to patent their own apparatus for the purpose. In 1887, some publicity was given to the fact that Dr. W. L. Hollister of Austin had purchased an apparatus used for Bergeon's method of treating consumption by "gaseous enemata."

In the early months of 1890 there was a severe epidemic of influenza or "la grippe" throughout the region. Scarcely a village in the counties of Mower, Freeborn, Dodge and Steele escaped. At many schools only half of the pupils were present, and at one school in Austin only ten out of an enrollment of seventy were not affected. By February, 1890, the disease had subsided in Austin, and in Albert Lea, so that most of the seriously ill patients were in the small towns or in the country. Thereafter the disease recurred almost every winter in the various communities, but it was milder, of shorter duration, and affected relatively few persons.

Occasionally in the last decade of the century, schools were closed for short periods because of scarlet fever. Now and then some locality reported mumps, measles or whooping cough.

Gradually but steadily, improvement was brought about in measures for public health and public welfare. It has been noted that physicians who served as mayor of Austin were influential in this advance in the city. Dr. O. W. Gibson was a progressive mayor for three consecutive terms beginning in 1888. Dr. C. H. Johnson served six terms as mayor, and to him are credited the institution of various improvements, some of which promoted public health as such and all of them, public welfare: a sewer system, electric lighting, a viaduct, new fire-fighting apparatus, and extension of public utilities.

Organization of Medicine

Nothing contributed more to public welfare in Minnesota than the organization of medical practice. Organization resulted largely from awareness on the part of the accredited physicians of the menace of quackery, of the need for improved medical education, and the importance of greater solidarity among members of the profession. The solution of the triple problem was medical legislation and the formation of medical societies. It is not necessary to review in detail the medical legislation in the state. The well-meant but abortive law of 1869 (repealed the next year) instead of shutting out the quacks and itinerants, inadvertently, through a technicality, opened the field to them. This effort was followed by the effective laws of 1883 and 1887, and those enacted later in the century as new problems arose. The acts of 1883 and 1887 protected physicians and the public from quacks and incompetents, led to improvement in professional qualifications, and aided in closer association of physicians.

The established custom of intercounty practice throughout the state, wherever practicable, was a factor in fostering mutual respect and esteem among physicians and in promoting the formation of medical groups. Most of the well-known physicians of Mower County were called professionally into the adjoining counties, and the physicians of those counties were summoned into Mower County. For example, Dr. W. F. Cobb, in Mona, Iowa, from 1874 to 1895, was well-known and valued not only in two or more counties of Iowa, but also in Mower County, long before he established his residence in Lyle in 1895. Dr. C. A. Hegge and Dr. O. H. Hegge, who began practice in Austin in 1893, soon were answering calls in four counties in Minnesota and in three counties in Iowa.

An early sign of the changing attitude of physicians toward the art, science and ethics of medicine was the attempt to found county medical societies, a procedure that long had been urged by the American Medical Association and by the state medical societies. In Minnesota the work began in the eighteen fifties and sixties. By 1872 there were in Minnesota six county medical societies, all of which were affiliated with the Minnesota State Medical Society.

In addition to the few groups which then were component parts of the state medical society, there was organized in Minnesota in 1867 the Minnesota State Homeopathic Institute, and subsequently there were various local homeopathic medical societies (city, county, and district) some of which had interest for physicians of Mower County. In 1869 the Minnesota State Eclectic Medical Society was founded, with various members from southern Minnesota. In 1871 the society met in Austin, at the office of Dr. C. H. Blecken, at which time Dr. P. C. Berry, of Austin, was admitted to membership.

Although the physicians of Mower County did not organize a county medical

society as a component part of the state medical society until after 1900, they were interested in medical organization at a much earlier date. In February, 1880, a meeting was held at which it was resolved to found a medical society that should include physicians from Mower, Freeborn, Fillmore and Steele Counties. Drs. L. D. Jackson, F. M. Johnson (C. H. Johnson did not come to Austin until 1884), and W. L. Hollister were appointed to correspond with the physicians of the other counties to enlist their interest. The name chosen was "The Southern Minnesota Medical Society." Perhaps this group was a forerunner of the Southern Minnesota Medical Association which was founded in 1892. Although the local society persisted, for a while it was rather loosely organized and did not meet often. There was, as late as 1896, when Dr. H. F. Peirson was president, what later was recalled as "the old Mower County Medical Society"—possibly a survival of the group organized in 1880.

Before 1900 several physicians of Mower County were admitted to membership in the Minnesota State Medical Society. It appears from entries in the *Transactions* of the state society that Dr. J. A. Allen of Austin was the first, in 1870; his name does not appear on the roster after 1874. Three members—Dr. L. D. Jackson, Grand Meadow, and Dr. W. L. Hollister and Dr. J. P. Squires, both of Austin, were admitted in 1880 (a fact significant when considered with the meeting held that year to organize a four-county society). Dr. Emma Backus Fairbanks became a member in 1885; Dr. D. F. O'Connor, Grand Meadow, in 1897; and Dr. W. F. Cobb, Lyle, and Dr. C. A. Hegge and Dr. O. H. Hegge, Austin, in 1898. Dr. W. W. Freeman, Grand Meadow, was admitted in 1900, and Dr. A. W. Allen, Austin, in 1901 or 1902, to be followed by many others after the organization of the Mower County Medical Society.

Various physicians of Mower County became founders or early members of the Southern Minnesota Medical Association, founded in the summer of 1892. At a meeting held in August, 1898, Dr. W. N. Kendrick, of Austin, was elected one of the vice-presidents. Also present from Mower County were Dr. M. J. Hart, Le Roy, and Dr. Albert Plummer, Racine.

The Mower County Medical Society

To discuss the formation of the Mower County Medical Society, which was founded after the turn of the century, goes beyond the nominal contents of this article (events prior to 1900) but since most of the organizers had settled in the county considerably earlier, some of them in the late sixties, the seventies and early eighties, the lists of members are of interest. The following statements, ending with an authoritative account, all are matters of record in one way or another. They are given here without controversial implication and without attempt to explain the apparent discrepancy.

October 3, 1902, has appeared in different accounts as the date on which the Mower County Medical Society was founded. From entries in the *Transactions* of the Minnesota State Medical Association and from an account in the general history of Mower County, of 1911, this date would seem to be correct.

There is evidence in the records of the state society that the county society was not in existence before June 18, 1902. In the report of Dr. R. J. Hill, treasurer of the state society, of that year, published in the volume for 1903 of the *Transactions,* appears the statement that on January 16, 1903, he "received of C. A. Hegge, Secretary of the Mower County Society, $44." In the same volume, Mower County is listed as one of the counties in which new societies had been formed as part of the new program of organization. The American Medical Association recently had been urging the organization of county societies as component parts of

the official state medical associations, as formulated in the new constitution and by-laws of the national association. Beginning in August, 1902, in Minnesota, Dr. W. S. Fullerton, acting for the Minnesota State Medical Association, was the organizer of the auxiliary county and district societies.

The following statement is taken verbatim from the *History of Mower County,* 1911, from a chapter that was edited by Dr. Arthur West Allen, of Austin.

MOWER COUNTY MEDICAL ASSOCIATION

In the preceding paragraphs has been related the story of the early physicians of Mower County. The present-day physicians are nobly following in their predecessors' footsteps. The Mower County Medical Association was organized October 3, 1902. The meeting was called to order by Dr. W. S. Fullerton, state organizer, and Dr. C. A. Hegge, the former being made temporary chairman and the latter temporary secretary. The officers elected were: President, William Hollister; vice president, W. F. Cobb; secretary, C. A. Hegge; treasurer, G. F. Schottler. The physicians present at the organization were: A. W. Allen, O. H. Hegge, C. A. Hegge, William Hollister, W. H. McKenna, F. Kimball Fiester, C. F. Lewis, H. F. Pierson, E. H. Washburn-Rodgers, O. C. Marcklien, George W. Gray, G. J. Schottler, W. W. Freeman, W. F. Cobb and W. A. Frazer. Since then the presidents have been: 1903, William Cobb; 1904, A. E. Henslin; 1905, H. F. Pierson; 1906, G. J. Schottler; 1907, W. A. Frazer; 1908, C. C. Leck; 1909, M. J. Hart; 1910, C. F. Lewis. The society has done much to sustain the ethics of the profession, to promote the sanitation of the county, to protect the health of the community and to guard against charlatanry in all guises and forms. The society is now constituted as follows: President, C. F. Lewis; secretary, Clifford C. Leck, Austin; other members, A. W. Allen, Austin; W. F. Cobb, Lyle; A. N. Collins, Austin; W. A. Frazer, Lyle; G. W. Gray, Brownsdale; M. J. Hart, Le Roy; C. A. Hegge, Austin; O. H. Hegge, Austin; A. E. Henslin, Le Roy; C. H. Johnson, Austin; R. S. Mitchell, Grand Meadow; Homer F. Pierson, Austin; G. M. F. Rogers, Austin; G. J. Schottler, Dexter; E. V. Smith, Adams; P. T. Torkelson, Lyle.

In the *Transactions* of the Minnesota State Medical Association, in the volume dated 1903, appears the following roster of the new Mower County Medical Society:

W. L. Hollister, Austin, *President*
C. A. Hegge, Austin, *Secretary*
W. F. Cobb, Lyle
F. E. Daigneau, Austin
Fanny K. Fiester, Austin
W. A. Frazer, Lyle
W. W. Freeman, Grand Meadow
G. W. Gray, Brownsdale
M. J. Hart, Le Roy
O. H. Hegge, Austin
A. E. Henslin, Le Roy
C. H. Johnson, Austin
H. L. Knight, Adams
C. C. Leck, Austin
C. T. (F.) Lewis, Austin
W. H. McKenna, Austin
O. C. Maercklin, Adams
H. F. Peirson, Austin
E. H. Rodgers, Austin
G. J. Schottler, Dexter

In the report of the Mower County Medical Society in the volume dated 1904, Dr. W. F. Cobb, Lyle, was listed as president, Dr. C. A. Hegge, secretary. Additional names on the roster were those of A. W. Allen, F. W. Davis, W. W. Kendrick, Benedick Melby (Hayfield), C. J. Maercklin, and F. W. Schultz (Waltham).

In 1955 Dr. O. H. Hegge, of Austin, prepared the following important account of the organization of the Mower County Medical Society, quoted exactly, which places the date of founding as April 8, 1904. Dr. Hegge made available to the present writer the charter which was issued by the Minnesota State Medical Asso-

---

Errors in initials and in spelling of surnames are given here as they appear in the printed account.

ciation, dated April 8, 1904, and signed by Dr. Thomas McDavitt, Secretary, and Dr. Charles Lyman Greene, President:

Organization of Mower County Medical Society.—March 16th, 1904, Dr. O. H. Hegge had occasion to go to St. Paul, and on the street he met Dr. Thomas McDavitt, secretary of the Minnesota State Medical Ass'n. The doctors were well acquainted, since Dr. Hegge had spent one year in St. Paul as assistant to Dr. Edward Boeckman. Dr. McDavitt and Dr. Hegge arranged to have lunch together at the St. Francis Hotel, and during the lunch hour they talked over the need for organizing a county medical society in Mower County. As secretary of the State Medical Ass'n., Dr. McDavitt was anxious to have a county society in every county where there was a sufficient number of physicians to make this plan feasible. Dr. Hegge went back to Austin determined to try to organize the Mower County Medical Society, if the idea met with sufficient encouragement from the other physicians in Austin and Mower County. After talking the plan over with his brother, Dr. C. A. Hegge, and other physicians in the county a meeting was called on April 8, 1904, to be held in the upstairs parlors of the Fox Hotel, and here the Mower County Medical Society was organized with Dr. O. H. Hegge as temporary chairman. Dr. Willis F. Cobb, an old and respected physician of Mower County, had previously been approached by Dr. O. H. Hegge, and Dr. Cobb had promised to become the first president of the newly organized society. Dr. C. A. Hegge was elected the first secretary and Dr. G. J. Schottler, of Dexter, Minnesota, treasurer. The Mower County Medical Society was thus started April 8, 1904, and Dr. McDavitt was notified of our organization and he consequently sent us the charter issued by the Minnesota State Medical Ass'n., of which the Mower County Medical Society is a component part. The Mower County Medical Society has continued to function for 51 years—monthly meetings are held except in the three warmest summer months.

The unit of medical organization is the *county* society. County Societies make up the State Association, and State Societies the American Medical Association.

At this writing, the Mower County Medical Society has functioned successfully fifty-three years and five months, from the date of the charter.

St. Olaf Hospital, Austin

To the vision and initiative of Dr. O. H. Hegge, of Austin, was due the founding of St. Olaf Hospital, which was opened to the public in the summer of 1896, then a small hospital of twenty-five beds. A little later there followed the organization of the St. Olaf Hospital Training School for Nurses.

The initial investment in the hospital was that of Dr. Hegge, "a small beginning, about $25,000," which soon was increased to more than $50,000 by public subscriptions, at first chiefly those of the Lutheran congregations of Austin and vicinity, later those of many other persons. A few years earlier the Drs. Hegge had a small private hospital of five beds in rented rooms upstairs over the offices of the *Daily Register* of Austin.

In the idea of a community hospital for Austin and the surrounding region Dr. Hegge had the full endorsement of his brother Dr. C. A. Hegge, and in the planning and work, his devoted aid. Fellow Lutherans, and numerous other citizens, gave sympathetic and practical help, and his professional colleagues in the city and the county, their interest and cooperation. Dr. Hegge has said:

"I founded, named, and financed the institution at first, and I also had the hospital incorporated as a Lutheran hospital, with adherence to aged medical practice. No lines were drawn as to color, creed, or nationality. All regular physicians, and their patients, were accepted and treated alike. The same is true today (1957). St. Olaf is essentially a community hospital, an 'open' hospital, where about thirty-five different doctors serve the public and the institution."

When St. Olaf Hospital was opened, Sister Lena Nelson, who had been at the head of the surgical department of the Deaconess Hospital in Minneapolis, was placed in charge. Later she returned to the Deaconess Hospital as director, and was replaced at St. Olaf Hospital by a hospital matron who had served in a similar position in Hillsboro, North Dakota.

Additional data taken from the county history of 1911 elaborate somewhat Dr. Hegge's account: The purpose of St. Olaf Hospital was not for private gain, but for service to the public. Patients were received on the recommendation of any member of the regular medical profession, on the approval of any member of the medical staff, or by consent of the majority of members of the board of trustees. Arrangements were made for admitting charity patients, without regard to religion, race or condition in life. Patients were privileged to summon any physician whom they preferred.

The first official members of the professional staff of the hospital were Dr. O. H. Hegge and Dr. C. A. Hegge. On the first board of directors were The Rev. J. Muller Eggen, of Lyle, President; The Rev. S. O. Rondesvedt, of Grand Meadow, Vice-President; The Rev. E. T. Rogne, of Austin, Secretary and Treasurer; P. K. Everson of Hustad, Iowa, and L. F. Clausen and Dr. O. H. Hegge, of Austin.

St. Olaf Hospital has grown from its modest beginning to a hospital of more than 180 beds (1957) and an approximate value of two million dollars. Four additions to the building have been made since 1900: in 1906, 1915, 1918, and 1955. The hospital serves a wide territory; patients come to it not only from Mower County but from neighboring counties in Minnesota and in Iowa.

At the Close of a Century

In 1856 Mower County had 127 miles of county roads, and no railroad, as compared with the present network of highways and lateral roads and the railway facilities. In 1856 the population of the county was a matter of hundreds; by 1859 it was 3,700; in 1957 (census of 1950) it is 42,277, and probably more. In 1856 Austin was a settlement of thirteen scattered homes and a few businesses. Today it is a thriving city (since 1857, the county seat) of more than 30,000 population, and is distinguished for civic, industrial and professional achievement. Some of the villages of the county developed correspondingly; some, as in all counties, became "ghost towns." In 1856, of the possibly seven physicians in the county, with the limited professional resources of the day, two were in Austin. Today there are in Mower County about thirty-five members of the regular profession, most of them in Austin, who have at their command every advance that has been made in the practice of medicine.

Biographical Sketches

About many of the practitioners of medicine in Mower County prior to 1900, as mentioned earlier in this account, there unfortunately is slight record. Concerning others, known and loved for their skilled and faithful service over many years, more, but not enough, is known. Too often the physician is unsung. All listed here, however, played a part, great or small, in the development of medical practice in the region.

— **Aldenkirk,** a homeopathic physician, a native of Germany, came to Le Roy from Winneshiek County, Iowa, in the spring of 1881, and began the practice of medicine. It is recalled that he had a fairly good office business. After about two years he removed to Postville, Iowa.

Abraham Orlenzer Allen, born in 1850 in Wisconsin, was one of the five children of Dr. Orlenzer Allen, pioneer physician of Austin in 1856, and Esther Almeda Coon Allen. Abraham O. Allen received part of his early schooling in Austin and perhaps his preliminary medical training from his father. In 1884 Dr. A. O. Allen was practicing medicine at Wolsey, Beadle County, Dakota Territory. In the official record of physicians of the Territory it was stated that he was graduated from Rush Medical College, Chicago, on February 16, 1886, and licensed in Dakota Territory, under the new territorial legislation, on March 22, 1886.

Dr. A. O. Allen was licensed in Minnesota under the Affidavit Law of 1887 and again, apparently, in 1889. For a few years he was in practice in Austin with his brother, Dr. A. W. Allen (*q.v.*). In 1893 he was listed as of both Austin, Minnesota, and South Sioux City, Dakota County, Nebraska. In 1902 he was recorded as of both Mountain Lake, Cottonwood County, Minnesota, and Hart, Oceana County, Michigan.

From 1898, for most of the time until his death at his home on October 13, 1913, Dr. Abraham Orlenzer Allen was a resident practitioner at Mountain Lake, Minnesota. In the last mention of his name in a medical directory he was designated "Abram Orrinzer Allen," and the name so appeared in his obituary in the *Journal of the American Medical Association* of November 8, 1913.

Arthur West Allen, a son of Dr. and Mrs. Orlenzer Allen, who came to Austin in April, 1856, was born in Austin in August, 1862, the youngest of the five children in the family. He grew up in the city and there received his early education. In 1885 he was graduated from Rush Medical College, was licensed in Minnesota on June 12 of that year, receiving certificate No. 1070 (R), and at once began the practice of medicine and surgery in Austin, where until his death in 1940 he was an honored citizen and physician. As noted, for a few years his brother, Dr. A. O. Allen, was in practice with him.

Dr. A. W. Allen served his city and county in various capacities. He was coroner for some years, a county physician, one of the earliest members of the Mower County Medical Society and automatically a member of the Minnesota State Medical Association and the American Medical Association. He encouraged the organization of St. Olaf Hospital and was one of the first to use its facilities in his practice. For a time he specialized in ophthalmology. For nine years he was Surgeon-Major of the Second Regiment of the Minnesota National Guard. He was local surgeon of the Chicago, Milwaukee and St. Paul Railway Company, and a member of the American Association of Railway Surgeons. For two years, about 1909-1911, he was president of the Austin Commercial Club. He was a member of various fraternal groups, among them the Masonic Lodge and the Benevolent and Protective Order of Elks, a charter member of the Austin Lodge of the Elks.

Although actively interested in civic enterprise and in politics, Dr. Allen, a Republican, never sought or accepted political office. Always outspoken, but moderate in expression, he energetically promoted the establishment of municipal waterworks at a time when Austin had only a pump at the corner of Main and Mill Streets, and urged the purchase of Sargent Springs (later City Springs), which came about in 1910; the paving of Main Street; and a better sewerage system. It is said that he always had in his mind the wants of the *growing* town, was truly forward looking in public matters. At a time when the Panama Canal was scarcely more than projected, Dr. Allen, on the invitation of his friend, Congressman James A. Tawney, accompanied a congressional committee to visit the Canal Zone.

For the first twenty years of his practice, Dr. Allen's experiences were the arduous ones of the pioneer physician in coping with lack of facilities, traveling with horse and buggy over dusty or muddy roads in open seasons, and with horses and sleigh over ice and snow. An excellent writer, in "The Country Doctor," a beautiful tribute to the early physician, he supposedly depicted his father. A few paragraphs from his pen appear in the chapter on medicine in the county history of 1911.

By 1939 Dr. Allen was in failing health. In that year he became an honorary member of the Mower County Medical Society and applied for honorary, or affiliate, membership in the state and the national medical associations. Early in 1940 he announced the association with him in practice of Dr. O. J. Johnson, of Lyle, Dr. Johnson concurrently to continue his practice in that village.

Arthur West Allen was married on September 14, 1905, to Nellie C. Sutherland, a native of Austin. There were no children of the marriage. When Dr. Allen died, on May 6, 1940, he was survived by Mrs. Allen. Her death occurred about fifteen years later.

It was written in 1911 and was said to the end, "Dr. Allen is a man who will not accept the praise offered him, but his true worth is written in the hearts of the people to whom he has ministered."

J. A. Allen, of Austin, was elected a member of the Minnesota State Medical Society at the meeting held in June, 1869, at Dresser Hall, Owatonna. His name did not appear on the roster after 1874. Apparently he was the only representative

from Mower County until 1880 when Dr. Lyman D. Jackson, of Grand Meadow, and Drs. William L. Hollister and James P. Squires, both of Austin, were admitted to membership. Nothing further has been learned about Dr. Allen. It is believed that he came to Austin in the late eighteen sixties.

Orlenzer Allen, the first physician to settle in Austin, Mower County, came to the city in April, 1856.

Born at Alfred Center, New York, March 17, 1826 (sometimes given 1830), he came west in 1842 with his parents and his twin brother Ormanzo to Milton, Wisconsin. There he attended Milton College and studied medicine with Dr. Rider. In 1856 he was graduated with honors from Rush Medical College, Chicago. He at once took a short graduate course at the New York College of Physicians and Surgeons, on completion of which he began medical practice at Milton. Soon afterward he came to Austin with his wife and children and his brother Ormanzo, who was by then a lawyer. In this city and community the two brothers enjoyed parallel careers of distinction in their respective professions.

Orlenzer Allen was married in Wisconsin in 1847 to Esther Almeda Coon, a successful school teacher. There were five children of the marriage, four sons and one daughter, at least one of whom, Arthur West Allen, was born in Austin. Two of the sons, Abraham and Arthur, became physicians.

Dr. Allen's professional card, in the early days in Austin, announced him to be an eclectic physician. For several years he ran a drugstore in connection with his practice, as did many other physicians of that period. He rendered a various service, as physician, as coroner, and as one of the first physicians to give county aid to the poor. In February, 1859 he and Dr. Hiram L. Coon, also of Austin, presented bills to the county commissioners for this service. In his civic capacity Dr. Allen was county commissioner, justice of the peace, and alderman.

A good citizen and a physician of excellent judgment, Dr. Allen held the confidence and respect of the community. In later years it was written of him that he was a practitioner of "the kindly old school . . . an ideal country physician, kindly, self-sacrificing and able"; and of him and his wife, "Their good deeds will ever be remembered in the county."

Dr. Orlenzer Allen remained in Austin until 1870, when he returned to Milton, Wisconsin. His death occurred there, April 5, 1883, from pleuropneumonia.

Joseph Alloys, the first physician to practice medicine at Lansing, came to the village in 1857. He was then about sixty years old, a short, thickset man, who was a Catholic priest as well as a physician. He soon pre-empted the southeast quarter of section 1 in Lansing Township and began farming in addition to his professional work. It is said that he had a good medical practice and that he ably conducted his medical and clerical duties and his farm until about 1860, when he moved to Chicago.

G. M. Allsdurff (the name appears in various spellings), an early eclectic practitioner in Mower County, was born November 24, 1824, in Sparta, Crawford County, Pennsylvania. Information about his early education and his medical training is lacking. In the autumn of 1864, then nearly forty years of age, Dr. Allsdurff came to southern Minnesota and settled in Le Roy, in the portion of the village called the "old town," the only physician in the settlement at that time. Dr. J. C. Jones and his wife, Thomsonian physicians, had been in the locality since 1855, but on the arrival of Dr. Allsdurff, it is said, they gave up practice.

Happening to arrive during a severe epidemic of diphtheria, Dr. Allsdurff found himself in demand in the counties of Mower and Fillmore in Minnesota, and in the counties of Howard and Mitchell in Iowa, bordering the Minnesota line. Thus established, he continued in successful practice.

When the new village of Le Roy was laid out in 1867, Dr. Allsdurff opened an office there and in 1868 transferred his residence also. After the enactment of the Minnesota Medical Practice Act in 1883 he practiced under an exemption certificate, and was still in practice in 1902 and perhaps a little later, but not in 1904.

R. A. Barnes, born in the East in 1826, served as a surgeon in the Union Army during the Civil War. In the autumn of 1864 he settled in Austin, Mower County. His professional card stated that he had had experience in New York hospitals and that he had practiced in the Middle West, for some time at Mitchell, Iowa. In Austin, he served as county physician, as examiner on the United States Bureau of Pensions, and for many years as coroner. He died in Austin in January, 1878,

from apoplexy and paralysis of the left side at the age of fifty-two years, survived by his wife and two daughters.

Marshall T. Bascomb was born on November 18, 1851, in Mt. Vernon, Ohio, the youngest of the four children of Mr. and Mrs. Newell Bascomb, who in the autumn of 1854 were pioneer settlers in Oronoco, Olmsted County, Minnesota. He obtained his early education in the schools of Oronoco and of Rochester, and in the early eighteen seventies studied medicine at the University of Michigan. In 1875 he was married to Ella B. Cook, daughter of Mr. and Mrs. Martin W. Cook, of Rochester.

There is record that from 1877 to 1879 Dr. Bascomb practiced medicine in Brownsdale and in Grand Meadow, Mower County, and that for a year or more in 1880 and 1881 he practiced at Eau Galle, Wisconsin. In the latter year he enrolled at Western Reserve University, Cleveland, Ohio, from which he received the degree of doctor of medicine on March 14, 1882. Immediately afterward he went to Clark, Clark County, Dakota Territory; under the territorial medical practice act of 1885, he registered on July 9, 1885. While in Clark he was a member of the state board of health, in 1893-1894, and county coroner, 1894.

In 1895, Dr. Bascomb returned to Olmsted County, settled in Pleasant Grove, and operated a drugstore as an adjunct to the practice of medicine. He was an active member of the Olmsted County Medical Society and the Southern Minnesota Medical Association; served as local county physician; was active in numerous fraternal organizations. He was respected and well liked, as a citizen and a physician. He died January 28, 1899, in his forty-eighth year, survived by his wife, two sons, his mother, a sister, and a brother, Edward G. Bascomb, of Austin. E. G. Bascomb was the husband of Carrie M. Wheat, daughter of Dr. and Mrs. John N. Wheat, of Austin.

John S. Beagle, born in 1873, was graduated in 1896 from the Hahnemann Medical College of Chicago, and was licensed in 1897 as a physician in Minnesota. It has been said, erroneously, that he practiced medicine in Chatfield and also in Spring Valley. Dr. Beagle stated in a letter of August 11, 1943, to the writer of the early medical history of Fillmore County, that although he spent his boyhood and youth in Spring Valley and was graduated from the Spring Valley high school, he never was a resident physician anywhere in Fillmore County, but in 1897 began to practice his profession in Rose Creek, Mower County. In 1898 he was married to Fantine Van Loan of Hamilton, Fillmore County. "My life and experience have been those of the ordinary country doctor, beginning in the days of horse and buggy travel." In 1909 Dr. Beagle moved from Rose Creek to Sidney, Montana, where, with the exception of a temporary removal to California, in 1926, he remained.

Charles Severin Beaulieu (1835-1896), physician, preacher, newspaper editor and sometimes politician, was a colorful figure in southern Minnesota from 1868 to perhaps 1890. Eckman and Bigelow gave a detailed account of his life in their history of medicine in Dodge County.

Born in the Department of Loire, France, in 1835, he came to the United States in 1840 with his parents; his father was a political exile. He spent ten years of his boyhood in Canada, and returned to Oswego County, New York. Later he was educated in France for the priesthood, but subsequently renounced his faith and became a convert to Protestantism. Perhaps in France he received his training in medicine. In 1861 he raised a company, of which he became first lieutenant, in the 24th Regiment of New York Volunteers. He was promoted to captaincy, fought in the second battle of Bull Run and in several minor engagements. Probably during his military service he acquired further medical and surgical experience. Some time after leaving the army in 1863 he went to Indianapolis, where he practiced medicine.

In 1868, Dr. Beaulieu settled in Concord, Dodge County, Minnesota, and remained there until November, 1880, when he accepted a call to Brownsdale, Mower County, as pastor of the Christian Church. "He seems to have been a curiously erudite man who could pactice medicine or occupy a pulpit with equal facility." In October, 1882, he was ordained in Minneapolis as evangelist of the Christian Church. During his years in Brownsdale, he practiced medicine and was licensed in the state under exemption certificate No. 723-3 on December 31, 1883. While in that village he became chaplain of the Colonel Henry Rogers Post No. 11 of the Grand Army of the Republic. This post was named for Lieut-Col. Henry C. Rogers (1834-1871) of Brownsdale, who had settled there in 1856. There is record that

Dr. Beaulieu had served as Lieutenant-Colonel of the 9th Minnesota Regiment of Volunteer Infantry, and that he was Secretary of State of Minnesota (1868-1870).

When Dr. Beaulieu left Brownsdale and Minnesota is not known, but he was living in New Haven, Franklin County, Missouri, in 1896. It was reported that he ran the village newspaper and preached in the Christian Church, but that he never practiced medicine in Missouri; in fact, it was not known in the town that he was a physician. He died in De Soto, Missouri, on December 15, 1896. He was married four times; the third wife, whom he married perhaps about 1878, was Lena Green Slocum, widow of Dr. Julius Franklin Slocum (1843-1874), of Marion, Olmsted County. Dr. Slocum was a native of Mantorville, Dodge County, member of a well-known pioneer family.

M. D. Bedal, a graduate of the Chicago Medical College, opened an office in Rochester, Minnesota, in June, 1874, having just completed three years in Cincinnati, Ohio, which he spent attending lectures and practicing in the hospitals. It was reported in Rochester, in the usual manner of newspapers of the time, that he was a young physician of superior attainments and excellent natural abilities. Within a few months he proceeded to Brownsdale, Mower County, where he practiced until the spring of 1876, when he removed to Tekamah, Burt County, Nebraska.

This Dr. Bedal should not be confused with Dr. S. L. Bedal, who spent his boyhood in Olmsted County and read medicine with the Drs. E. C. and E. W. Cross of Rochester in the late sixties or early seventies; nor with Dr. Sylvester S. Bedel, graduate of the Chicago Medical College in 1871, who was in Albert Lea from 1872 to 1874.

Mention has been observed of a **Dr. Bedell or Bidell,** a graduate of a Chicago medical school, who was in Grand Meadow a year or two, probably in the seventies, and went on to Dakota. Record has not been found of such a physician being licensed in Dakota Territory under the medical practice law of 1885.

Erastus Belden and his son **Wallace P. Belden** were pioneer physicians who were known in Fillmore, Mower and Freeborn Counties. Erastus Belden spent some years in Frankford, Mower County; W. P. Belden lived chiefly in Spring Valley, Fillmore County.

Erastus Belden, son of Emanuel Belden, of English descent, was born March 26, 1809, and his wife, Julia Ann Lyons Belden, March 30, 1811; both were natives of New York. Dr. and Mrs. Belden, about 1835, with three young children journeyed to Ohio in search of a new home. After the birth of a fourth child at Elyria, Ohio in 1837 they returned to New York, where they remained until 1853. In that year with their son, Wallace, "a qualified physician," and two younger children, they came into southern Minnesota and shortly afterward settled in the vicinity of Hamilton and Spring Valley. A few years later they moved to Frankford, Mower County.

When Dr. Erastus Belden died at Frankford in February, 1867, the *Rochester Post* paid tribute to him as "a skillful surgeon and a thoroughly posted physician of the old school." He was buried in the Frankford Cemetery, where a large inscribed boulder marks his grave. His wife died a year later in Rochester, Minnesota. (For greater detail, see medical history of Fillmore County.)

Howard Bell, a graduate of the Medical Department of the University of New York City in 1884, was licensed on March 10, 1885 to practice in Minnesota, receiving certificate No. 1008 (R). At that time he was living in Lanesboro, Fillmore County. Little information about him has been available, and the length of his residence in the state is uncertain. It has been learned that for a time in 1885 and into the spring of 1886 he was in partnership with Dr. F. A. Blackmer, in Albert Lea, Freeborn County, and that around 1888 he was briefly in Mower County. Judging from the evidence of official medical directories, he left Minnesota early in the nineties, or sooner, and returned to the East. For many years, until his death in 1923, he was in Delhi, New York.

P. C. Berry, an eclectic practitioner, first visited Austin in 1869. He returned in 1870 and remained for several years. His wife, who at about this time became qualified to practice, assisted him and "offered her services to the ladies of the town." In 1871 Dr. P. C. Berry became a member of the Minnesota State Eclectic Medical Society, at a meeting held in the office of Dr. C. H. Blecken in Austin.

— **Bingham,** said to have been newly graduated from Rush Medical College, was the second physician, from approximately 1865 to 1867, to settle in Le Roy. Mower County, where he was introduced by the Messrs. Coleman. In different accounts it was stated that from Le Roy he removed to Lanesboro, Fillmore County. Possibly he was the Dr. D. W. Bingham who was in Winona in 1865.

The *National Republican* of Preston, Fillmore County, on January 24, 1873, referred to Dr. Bingham as assisting Dr. James Madison Wheat, of Lenora, in performing amputations of a hand and a foot on January 1, 1873; and in another column in the same issue, "We regret to learn of the death of Dr. Bingham, of Lanesboro, by smallpox. Three other cases are reported in that village today."

C. H. Blecken, an eclectic physician, practiced in Austin in 1871. In that year, as has been mentioned, the Minnesota State Eclectic Medical Society met in his office, and at this meeting Dr. P. C. Berry, of Austin, was granted membership. Dr. C. H. Blecken was mentioned briefly in the history of medicine of Goodhue County as having been one of the first three or four medical newcomers in Red Wing in the sixties.

F. Brewer practiced medicine in Austin in 1863, and ran a drugstore and bookstore in connection with his practice.

George S. Brigham, a graduate of the Medical Department of the University of Vermont in 1870, came to Austin from St. Albans, Vermont in 1876 and remained until September, 1878, when he settled in St. Cloud, Stearns County, having "purchased Dr. MacDonald's practice." There is mention of the birth of a son to Dr. and Mrs. Brigham in May, 1880, of Dr. Brigham's having set a broken arm, and, in September, 1881 with Dr. McMasters, having "amputated the leg of an Albany man." In January, 1883, he was appointed examiner for the United States Bureau of Pensions and with two other physicians was to form the examining board of St. Cloud. In June, 1883, he was admitted to the Minnesota State Medical Society and December 31, 1883 was licensed in the state, receiving certificate No. 578 (R). In 1892 he was elected city physician of St. Cloud.

David A. S. Britts came to Brownsdale, Mower County, in July, 1876, and remained there until 1880, except for a few months in 1879 which he spent as assistant surgeon at the Lanesboro Sanitarium with Dr. David Frank Powell (among whose "border cognomens" were White Beaver, the Surgeon Scout, Mighty Medicine Man, and Fancy Frank, some given by his Indian friends and some by his contemporaries among the white population). Dr. Britts became well known in southern Minnesota; several biographical accounts of him have appeared in the medical histories of Olmsted, Fillmore and Dodge Counties and in general county histories.

David Britts was born March 1, 1844, in Montgomery County, Indiana, and lived in Wisconsin from early childhood to 1862 when he came to Dodge County, Minnesota with his parents. Soon afterward he enlisted in Company M of the First Regiment of Mounted Rangers and with it served in the war against the Sioux Indians. This period was followed by military service with other regiments. After his discharge from the army because of disability incurred in the service, he attended the seminary at Wasioja, obtained his medical training at the Chicago Medical College and began practice at Marion, Olmsted County in the early seventies. In Brownsdale November 23, 1879 he was married to Alice M. Stevens of that village (in one account her name was given as Ella (Stevens) Hamlin).

In 1880, Dr. Britts went from Brownsdale to Clearwater, Wright County. In 1887 he was licensed to practice under an exemption certificate. Prior to 1904 he settled in Minneapolis. His name was included for the last time in the 1914 edition of the directory of the American Medical Association.

A. M. Brown came from Marble Rock, Iowa, to Lyle in 1883 and practiced there for a short time.

John W. Burchard practiced medicine in Brownsdale in 1891, later returning to South Dakota. He was for a time the editor of the *Brownsdale News.* It has been noted that John W. Burchard, Carthage, Miner County, Dakota Territory, a graduate of the University of Buffalo, New York in 1884, was licensed in Dakota August 27, 1887.

President's Letter

VARIATIONS ON AN ESSAY ON POLITICS

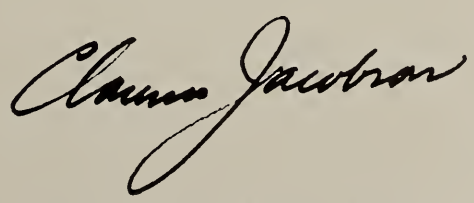
> "The wise know that foolish legislation is a rope of sand, which perishes in the twisting; that the State must follow and not lead the character and progress of the citizen; the strongest usurper is quickly got rid of; and they only who build on Ideas, build for eternity; and that form of government which prevails is the expression of what cultivation exists in the population which permits it."
>
> —Ralph Waldo Emerson, *Essay on Politics*

Why are congressmen so willing to go to great lengths to justify compulsory health legislation in the United States when the system is faltering in other nations? Ours is the only nation left in the world without a compulsory health care status.

In spite of this, we are now giving and will continue to give our people the highest standard of medical care in the world.

The medical profession is better informed today on health legislation than at any other time in its history. Our freedom to express our views on health legislation, and above all the privilege to participate as individual citizens in the promotion of good government, continues to prevail.

Seldom has more constructive effort been expended on behalf of the medical profession and its allies to bring to the attention of the people the danger involved in unwise legislation for care of the aged.



These efforts fortunately averted what, in all probability, would have been the first step toward a welfare state.

Both houses of Congress approved the amended version of H.R. 12580, and the Bill has received the signature of President Eisenhower.

The original Forand Bill can now be revealed in retrospect in the light of its imperfections and dire implications.

Once again, we have been given a precious respite which will enable us to build future plans based on broader and better documented surveys. Your attention is directed to the editorial page of the *AMA News* of September 6, 1960, which summarizes surveys recently completed on the subject; one from the National Opinion Research Center, University of Chicago; another entitled, "A Profile of the Aging U.S.A." from Emory University in Atlanta, Georgia. These surveys were made by interviewing the aged themselves with nearly parallel results. Similar surveys were made by the University of Kentucky and U. S. Department of Agriculture in a low income area, revealing that only 5.3 per cent of the aged men and 3.6 per cent of the aged women stated that they were unable financially to meet their health needs. We hope that the forthcoming White House Conference will reveal the whole picture, including our future attitudes toward a useful aging population.

Our sustained efforts to maintain high standards of practice, backed by sound political support will give our nation assurance of continued medical progress.

DELINQUENCY PRONE PERSONALITIES

I. Definitions and Types

The many social, judicial, and psychological problems involved in the phenomenon called delinquency have received considerable attention in recent years from the public and the press, various government agencies and officials, as well as from professional persons in psychiatry, psychology, sociology, law, education, and social work. What most concerns those representing society in general are the two questions: (1) what to do with the offender once apprehended and (2) what to do about an apparently increasing crime rate. These questions are now reflected in the actions of the courts which are not only concerned with establishing the guilt of the suspect but are also concerned with his rehabilitation. While the formalities of the law specify the procedures for establishing guilt, the rehabilitation of the offender is quite a new field.

Delinquency—and crime, however, are also matters which concern the theologian as well as the judge. Here the questions relate not directly to the individual's relations with society but to his relations with God and with himself. The ethical question is not whether a given act is illegal, but whether it is immoral. Most illegal acts would be considered immoral by churchmen, of course, but the reverse is much less frequently true. Guilt in this sense has more to do with its relationships to conscience and to will; and punishment is penance directed toward the restitution of God's grace.

Whichever of these views one may emphasize—and they are closely interwoven in this country, further questions arise: What leads to such behavior? How may it be prevented? How may the offender be rehabilitated? These are questions of learning; since the culture, whether in its secular or theological influences, aims to teach children to be governed by certain rules and principles.

An understanding of the dynamics of character formation not only focuses upon learning but also introduces the questions of constitutional pre-disposition. Therefore, both the possibility of a learning failure and the possibility of a constitutional failure might explain delinquency. On the other hand, there are those who emphasize that particular social stresses operating in given subcultures tend to produce aberrant behavior. In its extreme, this view suggests that whatever the individual's personality may be, the critical factors are those environmental situations which mold behavior along destructive lines. Much sociological research has shown that there is high association between crime and circumstance.

There are no conclusive research data to support any bias. The broadest generalization that can be made is probably that some concatenation of personality characteristics in a given social situation leads to delinquent behavior as one manifestation of a generally unhealthy personal-social interaction. We do not know precisely the nature or development of these personality characteristics, nor do we know exactly the threshold of social stress required to precipitate antisocial behavior. A reasonable hypothesis might be that in some constellations of personal dynamics, the individual needs little "real" threat to act, since the degree of psychopathology is so acute, his distortion of reality so great, and the act so idiosyncratically meaningful, that asocial or antisocial behavior is a highly probable outcome. In other cases, there appears to be evidence that whatever an individual's emotional disposition, experiences and stress of specific sorts are likely to produce criminal behavior whatever internal factors may be present.

Wirt, Briggs, and Golden,† in a recent research design, have stressed that the study of delinquency becomes obscured if the symptom of antisocial behavior is set apart as the defining criterion of some supposed personality type. Delinquency is a social criterion, describing persons who have trouble with the law. Some individuals are more likely than others to develop antisocial patterns, but to understand them we must not lump them all together, but rather refine the subgroups contributing the

largest numbers of delinquents. Wirt, Briggs, and Golden assign these to five general categories as follows:

1. *Diagnostic Category One.*—Delinquency primarily due to lack of emotional integration of the family. Such families provide ineffective example setting and disciplining for developing a social conscience. The family is hence an ineffective mediator of positive social values and the youngster is receptive to the least desirable influences emanating from associates and mass media of communication.

2. *Diagnostic Category Two.*—This includes cases where the antisocial disorder is primarily the result of the child responding to an integrated home, but where the child fulfills the conscious or unconscious antisocial impulses and desires of the parents. Such families have been most intensively studied by Johnson and Szurek.*

3. *Diagnostic Category Three.*—This includes those cases where antisocial behavior is primarily the result of disorder within the child. For example, where the siblings may be making an adequate adjustment, but the delinquent youngster suffers from a sociopathic, schizophrenic, neurologic, low intellect, or severe neurotic syndrome promoting antisocial behavior.

4. *Diagnostic Category Four.*—This includes the adolescent without major home or personality disorder whose normal hyperactivity and rebelliousness cannot be constructively integrated by his present environment because of a lack of acceptable outlets.

5. *Diagnostic Category Five.*—This includes those children whose delinquency is largely a result of efforts to seek or maintain status in their peer group.

Subsequent articles deal with each of these syndromes and with methods of diagnosis and treatment.

HERITABLE DEFECTS IN ERYTHROCYTE METABOLISM, WITH SPECIAL REFERENCE TO HEMOLYTIC SYNDROMES

Erythrocyte glucose-6-phosphate dehydrogenase (G-6-P. D.) deficiency is associated with increased susceptibility to hemolysis following the ingestion of various drugs or fava beans and during the course of viral and bacterial infections. In addition, this enzyme deficiency is associated with certain cases of non-spherocytic congenital hemolytic anemia.

This enzyme deficiency is genetically determined and is probably due to a sex-linked gene of intermediate dominance. The incidence of this trait varies, being in excess of 10 per cent among American Negroes and Caucasians of Oriental, Jewish, Greek and Sardinian extraction, while it is uncommon among Javanese and South American Indians and rare among Western Europeans and Chinese.

Studies of G-6-P. D. deficiency afford a model for examining the nature of gene action in man.

Evidence has been obtained that this genetically determined enzyme deficiency is more severe in affected Caucasians than in affected Negroes. In addition, the expression of this trait is variable in different tissues of an affected subject. Thus, in affected Negroes and affected Caucasians, G-6-P. D. activity is lower in erythrocytes than in leukocytes, platelets or liver.

To elucidate the mechanism by which this mutation gives rise to G-6-P. D. deficiency, studies have been made of the properties of this enzyme in crude hemolysates and purified preparations from red cells of normal and affected Negroes. The normal and mutant enzymes have been found similar in catalytic and physiochemical properties. However, the mutant enzyme is more readily inactivated by stroma than the normal enzyme. This inactivation is blocked by triphosphopyridine nucleotide or nicotinamide. It appears that the mutation involves a decreased stability of G-6-P. D. in the crude cell lysate which is not detected upon purification of the enzyme.

A simple assay system has been devised which is reliable in detecting subjects with a marked G-6-P. D. deficiency.

ACQUIRED VIRILISM

Excessive androgen production resulting in masculinization characterizes several well known disorders of the ovary and the adrenal cortex. However, few virilized women seen in clinical practice have a known pathologic entity such as congenital adrenal hyperplasia, arrhenoblastoma or adrenocortical tumor. Many patients presenting problems of hirsutism, menstrual irregularity and infertility have no demonstrable endocrine defect, or if abnormal hormone secretion is present, the source and nature of the defect may be difficult to identify. Of these patients some have polycystic ovaries, and the clinical remission which may follow wedge resection is suggestive evidence that the ovary is the source of the virilizing hormones. However, cystic ovaries have been observed in some patients with known virilizing disorders of the adrenal, and fractionation of 17-ketosteroids from urine of virilized patients with cystic ovaries has yielded results interpreted by some to indicate that hypersecretion of adrenal androgens is the real cause of the syndrome. On this basis the use of glucocorticoids has been advocated to suppress the adrenal hyperfunction and thus correct the hirsutism and the ovarian dysfunction.

The mechanism by which excessive secretion of adrenal androgens might lead to altered ovarian histology and function is speculative. It has been stated that the hormonal hypersecretion in the adrenogenital syndrome suppresses pituitary gonadotropin, thus leading to ovarian hypofunction. Yet several investigators have reported that hypersecretion of pituitary gonadotropin, primarily ICSH, occurs in patients with the Stein-Leventhal syndrome. The latter finding is compatible with the observation that virilization and polycystic ovaries can be induced by prolonged administration of chorionic gonadotropin, a hormone with biologic effects similar to those of ICSH. It seems unlikely that an adrenal secretion, suppressive of gonadotropic function, could produce ovarian changes which are more likely to result from excessive or unbalanced gonadotropin secretion.

Evidence is lacking that the virilizing hormones from the adrenal actually suppress pituitary gonadotropins. Of five adult patients with untreated adrenogenital syndrome studied by the writer, all excreted normal amounts of urinary gonadotropins and none had clinical evidence of ovarian function. With adrenal suppressive therapy gonadotropin titers of these patients fell as ovarian function was restored. In mildly virilized women, with or without polycystic ovaries, gonadotropin titers are generally within the normal range and glucocorticoid therapy, with sustained suppression of 17-ketosteroid excretion, produces no significant change in total gonadotropin levels although improvement in ovarian function results in some cases.

This evidence that gonadotropins are not suppressed in virilized patients raises the question of what affects may be observed by treatment which does suppress gonadotropins. Estrogen, the most potent inhibitor of gonadotropins, has been found to reduce to a significant degree the urinary 17-ketosteroid levels in most virilized patients. With prolonged therapy reduction in size of the enlarged polycystic ovaries and some improvement in hirsutism have been observed. Although these results suggest that a virilizing ovarian secretion has been suppressed, similar effects of estrogen have been observed both in normal subjects and in women excreting excessive amounts of 17-ketosteroids of adrenal origin. The mechanism of action of estrogen, now considered to be non-specific, is dependent upon increased plasma binding of 17-ketosteroid precursors and a decrease in the rate of their degradation.

Acquired virilism of mild degree is a common clinical complaint. Although in many cases no endocrine etiology for the masculinizing tendency can be demonstrated, in others increasingly specific analysis of blood and urinary steroid levels, especially when combined with observations of the effects of adrenal stimulation and suppression, have demonstrated otherwise obscure variations from normal. Review of such studies in 100 virilized patients examined in the Endocrine Clinic of Henry Ford Hospital failed to reveal any endocrinopathy in 40. Adrenogenital syndrome was diagnosed in six and gonadal dysgenesis in two. There were 25 patients with polycystic ovaries who excreted quantitatively normal amounts of urinary 17-ketosteroids and 17-hydroxycorticoids, and whose urinary steroid responses were normal both to administered ACTH and to suppression with glucocorticoids. The remaining 26 patients, considered to have adrenocortical dysfunction characterized by hypersecretion of androgens, had greater than normal amounts of 17-ketosteroids in urine while 17-hydroxysteroid levels were normal. The elevated

androgen/glucocorticoid ratio was maintained during stimulation with ACTH, and adrenocortical function could be suppressed in all cases by administration of glucocorticoids, excluding functioning adrenal tumors from diagnostic consideration. However, abnormal levels of pregnanetriol, the hallmark of congenital virilizing adrenal hyperplasia, were not encountered.

That these are two clinically significant groups of patients—those with polycystic ovaries without adrenocortical dysfunction, and those with adrenocortical dysfunction with or without polycystic ovaries—is suggested by the results of therapy. Prolonged adrenal suppression by oral glucocorticoid therapy proved beneficial only in the adrenocortical dysfunction group where improvement occurred in two-thirds of the cases. When polycystic ovaries were present, wedge resection was followed by a return of ovulatory menses or fertility in 20 of 22 cases, even when adrenocortical dysfunction was considered the primary disturbance. In the absence of adrenal dysfunction, glucocorticoid therapy led to disappointing results, but in properly selected cases regulation of menses and diminishing hirsutism was achieved. In some patients suppression of the elevated 17-ketosteroids has been observed long after glucocorticoid therapy is discontinued. Ovarian wedge resection does not lower total 17-ketosteroids, nor reduce the hypertrichosis.

Detroit, Michigan

THE HONORARIUM

Webster's Dictionary defines an honorarium as an "honorary payment or reward usually in recognition of gratuitous or professional service for which custom or propriety forbids any fixed business fee to be set or for which no payment can be enforced at law."

Such is the definition, but when, through common courtesy, may an honorarium be omitted? When a speaker comes from a short distance with little or no loss of time from his work, the command is less; whereas, when the individual comes from a great distance with a loss of time from his business, a suitable honorarium is obligatory. This philosophy has met with general acceptance.

Recently, honorariums have been suggested and granted under unusual circumstances. An honorarium was suggested for a medical speaker who participated in a medical program in his own city. Honorariums have been granted by a local medical group to speakers who journeyed about ten miles to address their meetings. There is some question as to whether or not this procedure increased the prestige or attendance at the meetings, since the subject matter, as well as the speaker, was familiar to many of those present.

What has happened to the previous gracious acceptance by speakers to address organizations within their area without fee? Is this to be a thing of the past, and are we to pursue the philosophy of Trade rather than of Profession?

It may be well again to read the Hippocratic oath and accept again our responsibility—

"To teach them this art, if they require to learn it, without fee or indenture; and to impart precept, oral instruction and all other learning to my sons, to the sons of my teacher and to pupils who have signed the indenture and sworn obedience to the Physicians' Law."

Anonymous

Editor's Note: The anonymous author of the preceding editorial points out a difference between speaking before a medical group for pay and speaking to advance medicine. He apparently laments a token recognition of the long hours of creative work which must precede the presentation of a scientific manuscript. From an editor's viewpoint, the predominant drones in our medical societies might cultivate a much keener appreciation of their contributing colleagues' efforts. The original articles in Minnesota Medicine cost each of the authors over $1,000.00. The society of 3,000 recipients of these gifts should be able to afford 100 free reprints for the physicians who prefer to practice rather than preach the Hippocratic precepts.

ANALYSIS, REVIEW AND EVALUATION OF CLINICAL PRACTICE IN THE HOSPITAL REVIEWED

Only physicians are capable of judging what is or what is not good medical practice. Patients and hospital personnel may learn to recognize good practice, but only the physician can accurately evaluate its quality, is the view expressed by Kenneth B. Babcock, M.D., Director of the Joint Commission on Accreditation of Hospitals, in the August *Bulletin* of that organization.

Member organizations of the Joint Commission include the American College of Physicians, American College of Surgeons, American Hospital Association and the American Medical Association.

The opinions of individual physicians vary and rightly so. For that reason, the Commission places heavy emphasis on group participation in evaluating clinical practice. It is the responsibility of the entire Active Medical Staff to analyze, review and evaluate the clinical practice in the hospital and to insist on high standards of performance from each of its members.

This responsibility is not easily discharged, points out Dr. Babcock. It requires hours of work which the busy physician can ill afford to spend and which is usually done at the expense of his personal pleasures. It requires an objectivity which is perhaps even more difficult to achieve. To judge the work of a colleague on a fair, unbiased, impartial level calls for the intelligence and wisdom of a Solomon. That this is so well done in thousands of hospitals can be attributed to the integrity, effort and persistence of each member of the medical staff.

Essentials

In order to evaluate clinical practice, Dr. Babcock enumerates the following essentials:

1. *Reliable Medical Records.*—There must be evidence on the medical record that the diagnosis was made on the basis of information given by the patient in the history, a careful physical examination, and a scientific interpretation of the findings. There must be sufficient data recorded to justify the physician's treatment of the patient and the results. For the sake of both the group whose responsibility it is to review the record and the physician whose performance is being evaluated, a good medical record is indispensable.

2. *Reliable Reports of Diagnostic Tests.*—The physician must rely on the accuracy of reports on laboratory and diagnostic tests. The medical staff cannot supervise all these areas, but it has a responsibility to make certain that there is supervision. This is done by recommending the appointment of qualified individuals to head these departments and to designate those on the staff qualified to interpret electrocardiograms, x-rays, and other diagnostic tests. If laboratory work is done outside the hospital, it must be made certain that these laboratories are government approved, licensed and under the direct supervision of a pathologist.

3. *An Organized Medical Staff.*—To insure a continual orderly process of evaluating clinical practice, the medical staff must be formally organized. This provides a framework in which the duties and functions of the staff can be carried out. The medical staff may decide to delegate the responsibility of clinical review to committees, to clinical departments or to the staff as a whole. Only the individual medical staff can determine the method which will be most effective in the local situation.

4. *A Competent Medical Staff.*—Though listed fourth, the most important factor in evaluating clinical practice is a competent medical staff. The quality of medical care in the hospital is in direct ratio to the knowledge, experience and ability of the members of the medical staff. The judgment necessary to evaluate clinical practice depends entirely on the ability of those who are doing the evaluating.

This makes the appointments to the staff and the delineation of privileges so important. To do this fairly and objectively, the medical staff should set up a system to evaluate each applicant and determine his hospital privileges on the basis of professional competence. Individual character, training, experience and ability should be the criteria for selection. Under no circumstances

should the accordance of staff membership or professional privileges in the hospital be dependent solely upon certification, fellowship or membership in a specialty body or society. Neither should appointments be denied on the basis of hospital bed capacity or selfish competitive motives on the part of the staff.

Although the primary purpose of clinical review is to achieve and maintain high standards of patient care, the process also serves as a means of evaluating the performance of individual staff members. The judgment, ability and competence of a staff member can be assessed by his methods of diagnosis, his skill in treatment and his ability to recognize situations which call for consultation. These facts should influence the decision to extend or limit his hospital privileges. Each member of the staff should be given the opportunity to realize his full capabilities, and at the same time safeguards must be established to protect patients. By good clinical review both patient and staff member profit.

The Commission in accrediting a hospital places great emphasis on the extent and care with which the medical staff reviews and evaluates clinical practice. Since good medical records, reliable diagnostic services and a competent, well organized staff are essential for good clinical review, these factors are closely surveyed. To be accredited, there must be evidence that the hospital medical staff is living up to its important responsibilities.

PHYSICIANS IN FIGHT FOR HEALTH CARE FOR THE AGED

On August 29, 1960, the Senate accepted H.R. 12580, 86th Congress, as reported by the Conference Committee, by a vote of 73 to 12. The House had accepted the measure, as reported by the Conference Committee, on August 26, by a vote of 368 to 17.

On August 23, 1960, the Senate rejected two major amendments to H.R. 12580, 86th Congress, as amended and reported by the Senate Finance Committee. Among those leading the fight in that Senate to defeat the "Anderson-Kennedy" amendment were Democratic Senators Harry Byrd, Virginia; Robert S. Kerr, Oklahoma; and Russell B. Long, Louisiana; and Republican Senators John J. Williams, Delaware; Carl Curtis, Nebraska; and Wallace Bennett, Utah.

Anderson-Kennedy Amendment

By a vote of 51 to 44 the Senate turned down an amendment sponsored by Senator Anderson, Senator Kennedy and eight other Democratic Senators which would have authorized hospital, nursing home, home nursing and diagnostic and x-ray benefits for nine million persons, aged sixty-eight and older, who are currently eligible for social security benefits. This plan would have been an addition to the Mills bill, as reported by the Senate Finance Committee, and would have been financed by a 0.5 per cent increase in the social security (¼ per cent increase for employee and employer). Proponents of the increase claimed it would finance the estimated $700 million needed the first year and the estimated cost of $1 billion after the first year.

Javits Amendment

Also on August 23, 1960, the Senate rejected the Javits amendment by a vote of 67 to 28. This amendment, which had the backing of the Administration, would have authorized a participating health benefits plan for 11 million persons aged sixty-five and over, who are not now receiving public assistance. This plan would have excluded individuals with annual incomes over $3,000 and couples with annual incomes of more than $4,500.

Long Amendment

The Senate passed by a vote of 51 to 38 (11 not voting) an amendment to H.R. 12580, 86th Congress, as reported by the Senate Finance Committee, which would eliminate the prohibition of payment to or care in behalf of individuals who are in tuberculosis or mental hospitals.

H.R. 12580, 86th Congress, As Passed by the Senate

At 8 p. m. on August 23, the Senate voted 91 to 2 in favor of H.R. 12580, 86th Congress, as amended by the Senate Finance Committee and as further amended on the floor of the Senate. Several amendments were made to this measure on the floor of the Senate following the defeat of the Javits amendment and the Anderson-Kennedy amendment. Only the Long amendment had any medical significance, however.

The bill, as passed by the Senate, consists of seven titles which would provide extensive amendments to the Social Security Act, including a federal-state matching grant program under which

medical care would be financed for the near needy aged and increased financial participation by the federal government in medical care programs under Old Age Assistance.

Title I

This title deals with coverage under the OASDI program. It contains amendments relative to the election of coverage by ministers, coverage for state and local government employees, employees of non-profit organizations, American citizens employed by foreign governments, domestic service and casual labor. It would provide that municipal and county hospitals would be considered as separate retirement systems, thus allowing them to make an election for social security coverage for their employees, notwithstanding the fact that the city or county has rejected coverage for its employees.

Title II

This title would amend the provisions dealing with eligibility for benefits.

Title III

Among other things, this title would provide for increases in benefit amounts for children of deceased workers.

Title IV

This title would eliminate the age fifty requirement for eligibility for disability insurance benefits. It would also eliminate the six-month waiting period for disability benefits for an individual whose disability had been terminated and who again became disabled within a five-year period.

Under existing law, disabled persons who return to work under a state approved vocational rehabiliation plan continue to draw benefits for up to twelve months even though they are engaged in substantial gainful activity. Individuals who rehabilitate themselves or who are rehabilitated under a program other than a state rehabilitation program do not have this benefit. This title would amend the law to provide that any disabled individual would be granted a nine-month (not necessarily consecutive) trial work period in which he could perform substantial services without losing his benefits. If he were determined to be able to engage in substantial gainful activity, his benefits would be terminated three months later. An individual whose condition improves, regardless of the trial work period, would receive benefits for three months following the determination of his ability to engage in substantial gainful activity.

This title would also liberalize the coverage requirement for certain individuals disabled before 1955. Existing law requires that to be eligible for disability benefits the individual must be fully insured, i.e., coverage in one out of every two quarters of coverage elapsing after December 31, 1950, or forty quarters of coverage, and have coverage for five years in the ten years preceding the onset of disability. This title would authorize benefits for an individual who had twenty quarters of coverage and coverage in all quarters elapsing after 1950 and before the onset of disability, if he had coverage for a minimum of six quarters.

Title V

This title contains amendments dealing with unemployment compensation.

Title VI

This title would revise and amend Title I of the Social Security Act under which Old Age Assistance is provided to authorize federal participation in approved state plans to furnish medical assistance on behalf of aged individuals who are recipients of Old Age Assistance and for individuals not on Old Age Assistance whose income and resources, as determined by the state, are not sufficient to meet the costs of necessary medical services.

While some of the requirements of the state plan for Old Age Assistance (including medical care) and those for medical assistance for the aged not under OAA would be identical, the amended bill would also establish specific requirements for each program. Those which would apply to both programs would require a state plan to provide:

1. That it will be in effect in all political subdivisions of the state.
2. For financial participation by the state.
3. That it will be administered by a single state agency.
4. A fair hearing for an individual whose claim for benefits is denied.
5. Such methods of administration as are found necessary by the Secretary of the Department of HEW for proper and efficient operation (except that the Secretary would not have

authority with respect to the selection, tenure of office and compensation of any individual employed under standards established by the state).

6. For making reports as required by the Secretary of Health, Education and Welfare.
7. For non-disclosure of information regarding applicants and recipients.
8. An opportunity for an individual to apply for assistance which would be furnished with reasonable promptness to those eligible.

State plans which would apply only to Old Age Assistance programs would have to provide:

1. That the state agency, in determining eligibility, would take into consideration any other income or resources of the individual.
2. Reasonable standards for determining eligibility, for and the extent of such assistance.
3. A description of services to be provided, including the utilization of other agencies providing similar services.
4. If the plan includes payments to individuals in private or public institutions, for the designation of a state authority which would be responsible for establishing and maintaining standards for such institution.

With the exception of No. 2, the above requirements are substantially similar to the requirements contained in existing law.

If the state plan also includes medical assistance for the aged not under Old Age Assistance, it would have to provide:

1. For the inclusion of "some" institutional and "some" non-institutional care and services.
2. That no fee or charge will be imposed as a condition of eligibility.
3. For the furnishing of assistance to residents of the state who are temporarily absent therefrom.
4. Reasonable standards for determining eligibility for and the extent of such assistance.
5. That no lien will be imposed on the property of the individual prior to his death and that there will be no recovery until after the death of such individual and his surviving spouse, if any, for any medical assistance correctly paid on behalf of such individual.

"Medical assistance for the aged" would mean "payment of part or all of the cost of the following care and services for individuals sixty-five years of age or older who are not recipients of Old Age Assistance, but whose incomes and resources are insufficient to meet all of such costs—(1) Inpatient hospital services; (2) skilled nursing home services; (3) physicians' services; (4) outpatient or clinic services; (5) home care services; (6) private duty nursing services; (7) physical therapy and related services; (8) dental services; (9) laboratory and x-ray services; (10) prescribed drugs, eyeglasses, dentures and prosthetic devices; (11) diagnostic screening and preventive services; and (12) any other medical care or remedial care recognized under state law."

Note: The bill as passed by the Senate contains no definitions or limitations on the above services as did the House-passed version.

As under the existing Old Age Assistance program, the federal government would contribute four-fifths of the first $30 ($24) of the average monthly payment per recipient, plus a "federal percentage" (50 to 65 per cent, depending on the state's relative per capita income) up to a maximum of $65 ($17.50-$22.75) per recipient.

In addition, the bill generally would provide an increase in the federal contribution of 50 to 80 per cent of sums expended in medical vendor payments up to a maximum of $12.

An alternative formula would provide for a 15 per cent increase in the "federal percentage" (from 50 to 65 per cent to 65 to 80 per cent) of amounts expended for medical or remedial care for Old Age Assistance recipients up to a maximum of $12 per recipient.

For those states which provide a program of medical assistance for the aged not under OAA, the federal government would contribute 50 to 80 per cent of the cost of the program.

Under both programs the federal government would also contribute one-half of the administration cost.

The report of the Conference Committee was accepted by the House on August 26 and by the Senate on August 29. The bill was sent to the President for his signature and became effective as of October 1, 1960.

Public Health

SURVEY OF DIETARY SERVICES IN MINNESOTA HOSPITALS

A comprehensive study of dietary departments in Minnesota hospitals has resulted in several recommendations which are now being submitted to hospital officials. These recommendations indicate that:

1. Intensified efforts should be made to attract students into the field of dietetics.
2. The interest of dietitians in giving service to small hospitals should be stimulated.
3. Educational programs should be instituted for non-professional food service personnel.
4. In planning new hospital construction or remodeling, more careful consideration should be given to the dietary department.
5. Programs and/or materials should be developed to acquaint hospital administrators, boards and others with the elements of a good dietary department and the role of a dietitian in the over-all operation of a hospital.

These survey results are reported in an article entitled, "The Dietary Department in a Small Hospital," by Ardelle Lofquist, B.S., Helen Knudsen, M.D., M.P.H., Bernard Wolcyn, Ph.D., and Robert White, Ph.D., which appeared in the *Journal of the American Dietetic Association* (37:32-37, July 1, 1960).

This study of dietary departments of Minnesota hospitals comprises one segment of a larger project known as "Demonstration and Study for Improving Patient Care" which has been supported by the United States Public Health Service and conducted by the Hospital Services Demonstration Program of the Minnesota Department of Health. Comparable studies were undertaken concurrently by consultants in each of four other paramedical areas: nursing anesthesia, medical records, medical technology and physical therapy.

This project was an outgrowth of earlier work supported by the W. K. Kellogg Foundation and aided similarly by the sponsorship of the Minnesota State Medical Association, Minnesota Hospital Association, Minnesota Department of Health and related professional groups, one of which was the Minnesota Dietetic Association.

The survey in 1957-58 was made by means of personal visits to each of 152 of the 181 licensed general hospitals in Minnesota. These hospitals with 135 beds or less were located in cities of 16,000 or under in population. In most instances the information was obtained from both the hospital administrator and the person in charge of food service by means of a questionnaire consisting of 177 items. These items were grouped into ten main categories: general information, menu planning, food purchasing, food storage, food preparation, food service to patients, modified (special) diets, food service to employees, records and sanitation.

The findings in the survey are reported to present a summary picture using two factors: (1) bed size, and (2) personnel in charge of dietary departments. The major findings of dietary departments of 152 general hospitals in Minnesota are given below:

1. Thirty-two dietitians and four home economists supervised 38 dietary departments of hospitals under 135 beds in rural Minnesota.
2. Hospital administrators are willing to give food service personnel time off with pay, travel and tuition expenses to provide them with short course training.
3. Administrators in 18 per cent of the hospitals expressed a need for more information on their own part regarding operation of a dietary department.
4. One-third of the 116 hospitals not employing a dietitian indicated that they would hire a dietitian, full or part time, if such were available.
5. Only 43 hospitals have written procedures to guide food service personnel in their day-to-day work.
6. Approximately one-half of the hospitals did little or no advance menu planning.
7. In approximately one-half of the hospitals, there was a storeroom solely for food and kitchen supplies, near, or in the kitchen. While refrigerator space appeared to be adequate, one-third of the hospitals did not have enough freezer space.
8. Of the ten major categories studied, cooks felt most competent and administrators were most satisfied with food preparation.
9. A centralized type of tray service was the most common method of assembling and distributing patients' food. Transporting of trays to patient areas was made by dumb-

waiter, unheated open carts or heated tray carts in descending order of occurrence.

10. The average labor time expended by food service personnel per meal served was 16.6 minutes.

11. In over one-half of the hospitals no standard diet manual was used as a guide for hospital personnel to aid in the interpretation of physicians' diet orders. Diet manuals were employed in almost all hospitals with dietitians.

12. Approximately one-fourth of the patients in hospitals were on modified diets (excluding soft and liquid diets).

13. Dietary instructions were given to patients in all hospitals employing dietitians. In hospitals without dietitians copies of diets were issued to patients by physicians, nurses and others.

14. All but one hospital served meals to employees; however, this service varied from the "help yourself in the kitchen" arrangement to waitress service in the dining room.

15. Smaller hospitals tended to furnish meals without charge to employees as a part of their salary. In larger hospitals, charges were made in a variety of ways: cash, meal tickets and salary deductions.

16. The dietary departments in only three hospitals used an operating budget; however, approximately one-third of the hospitals kept records regarding per day or per meal food costs.

17. A high percentage of the hospitals providing pre-employment physical examinations to food handlers repeated examinations annually. Seventeen hospitals required no physical examinations of food handlers.

Conclusions taken from the above findings are included here to provide a basis upon which to develop programs to meet the needs and achieve the aims of the Study.

1. Hospitals employing dietitians provided more complete supervision and management of the food service to patients and employees through:
   (a) Menu planning, which provided nutrients to meet the Recommended Dietary Allowances of the National Research Council and the use of selective and cycle menus;
   (b) Standardized recipes;
   (c) Purchasing according to preplanned menus;
   (d) Better utilization of equipment;
   (e) Records to indicate current food and labor costs;
   (f) Good sanitary practices;
   (g) Simplification and accuracy in therapeutic diets;
   (h) Patient education; and
   (i) Consulting with physicians.

2. There is a marked shortage of dietitians. Only one-third of all the hospitals in Minnesota had the services of a dietitian and the remainder were staffed by persons with essentially no professional training in dietetics.

3. A need exists for improvement in hospital dietary departments where dietitians or home economists are not employed. Hospitals recognize this need to improve their food service, as evidenced by interest in three essential activities:
   (a) Employing professionally qualified persons to direct dietary departments;
   (b) Participating in educational programs for non-professional food service personnel who are presently employed; and
   (c) Using educational materials to guide the operation of dietary departments.

4. Although most of the hospital dietary departments were adequately equipped, better utilization of existing equipment and facilities would improve the food service in many hospitals.

5. A more complete understanding of the various aspects of a good dietary department by hospital administrators, board members, medical staff, and nurses is a necessary first step in the improvement of food service in hospitals.

6. Many hospital administrators see the planning of therapeutic diets as comprising nearly the complete role of the dietitian and are unaware of the other contributions a dietitian can make toward the improvement of patient care and an efficient food service.

An approach has already been made toward dietary improvement of patient care in hospitals. A state-wide educational program through regional courses directed to food service personnel in hospitals is underway. Based on survey information the material is intended to cover normal nutrition, menu planning, modified diets and sanitation. Short courses have been held in four areas in Southern Minnesota; in addition, seven others are being considered for future courses.

The other suggested broad recommendations of encouraging dietitians to give service to small hospitals, planning for better food service facilities, recruiting new and "retired" personnel and informing administrators and hospital boards must be considered on long-term bases. Fulfillment can only be brought about by cooperative effort on the part of all organizations interested in gaining better hospital care and services for all patients.

Committee Action

TUBERCULOSIS CONTROL—PRINCIPLES

I. The eradication of tuberculosis continues to be dependent upon the continuation and intensification of the methods which have led to the present appreciable decrease in tuberculosis mortality, morbidity and rates of tuberculin conversion.

II. Control and eradication of tuberculosis continues to require, (1) intensive case-finding, (2) total treatment of active tuberculosis, and often certain inactive cases, (3) adequate follow-up examinations of all inactive cases, (4) education of the general public and professional groups, (5) rehabilitation in the broadest sense, (6) clinical and basic research, and (7) prevention.

III. Case-finding and diagnosis remain the cornerstones of tuberculosis control and require:
- (1) Routine chest x-ray examination of hospital and institutional admissions, including private and public general and specialized hospitals, penal institutions, nursing and rest homes.
- (2) Routine chest x-ray and tuberculin surveys when indicated and practical.
- (3) Routine chest x-ray studies of all positive tuberculin reactors, found on individual examinations or as the result of tuberculin surveys.
- (4) Life-time follow up examinations of all ex-tuberculous patients and all tuberculous contacts by at least annual chest x-ray examinations, if tuberculin positive, and annual tuberculin test, if initially tuberculin negative.
- (5) Encouragement of the private physician, by every means possible, to utilize the tuberculin test and chest x-ray routinely in the care of the apparently healthy as well as the ill patient.

IV. Treatment of the patient with active tuberculosis must be under continuous medical supervision and should be carried out:
- (1) In a sanatorium, especially during the initial period of treatment or in the infectious stage, or
- (2) In a general acute or chronic disease hospital, if a sanatorium is not available, provided isolation technique during the infectious period is practical, or
- (3) In the home if adequate facilities and competent continuous medical supervision are available, and only when protection of the public health is assured.
- (4) Recognition by the medical profession, through education, that initial therapy of the patient with active tuberculosis remains prolonged and that follow-up treatments and examinations, after the inactive phase has been attained, must be continued for the remainder of the patient's life.
- (5) Rehabiliation, in the broadest sense, remains a necessary part of the treatment of tuberculosis, since additional complications over and beyond the tuberculosis are frequently present. These special problems include alcoholism, silicosis, diabetes, gastrectomies, advanced age, chronic illness, etc.

V. Prophylaxis with chemotherapy should be considered carefully for, (1), children of pre-school age with positive tuberculin reactions, (2), adolescent children and adults with tuberculin conversion within one year, and (3), some patients with appreciable demonstrable inactive tuberculosis under special circumstances, as listed in IV (5).

VI. Education of the public, physicians and other professional groups to understand the documented basic principles of modern tuberculosis control, should be persistent and intensive.

VII. Research, clinical as well as basic, must be continued without restriction.

VIII. The following groups will continue to be involved, cooperatively, in the implementation of the above principles:
- (1) Health Departments.
- (2) Voluntary Tuberculosis Associations.
- (3) Medical Associations.
- (4) Sanatoria.
- (5) Universities and Colleges.
- (6) Welfare Departments.
- (7) Private-Public Hospitals and Private Physicians.
- (8) Auxiliary Professional and Lay Groups.

The Art of Medicine

PR

Carl H. Woyke, B.A.
Editor

WHEN YOUR PATIENTS AND THE PUBLIC ASK "WHAT IS THE AMA AND WHAT DOES IT DO?"

Do you tell them that the American Medical Association:

- **is an organization of more than 177,000 doctors who through their county medical societies comprise its membership . . .
- **publishes the weekly *Journal of the American Medical Association,* world's leading medical periodical; the AMA NEWS; ten monthly specialty journals; numerous books, pamphlets, reports . . .
- **provides timely information, through special councils, on such subjects as foods and nutrition, mental health, industrial health, rehabilitation . . .
- **sponsors national meetings at which thousands of physicians exchange ideas and learn "what's newest" in research and medicine . . .

One-fifth of the AMA's annual budget is spent to inform the public about health through such activities as *Today's Health* magazine, a question and answer service, TV and radio programs, films, exhibits, and a research service for news media.

The causes for which the AMA works—and fights—are those lying within its "field of competence": Medicine. They are always in the public interest. Even a partial list indicates their broad range:

- ***Increasing supply of physicians,* by encouraging young people to embark on medical careers, by working with the Association of American Medical Colleges to expand present schools and build new ones.
- ***Better distribution of medical services,* through a physician's placement bureau and an active program to help communities attract qualified medical people.
- ***Better patient care,* by working with other groups to maintain high hospital standards, and by encouraging construction of nursing homes.
- ***Exposing quackery* and alerting public to dangers of food fads, and unproven treatments.
- ***Promotion of voluntary health insurance,* through non-profit and commercial insurance organizations.
- ***Better medical care for the indigent,* through cooperation with state and local governments.
- ***Sound legislation,* such as: funds for hospital and medical school construction, improved pure food and drug laws, hazardous substances control laws, civil defense and medical stockpiling.

What is the Medical Profession Doing to Provide More Doctors for More People?

Do you point out that no group is more aware than the medical profession that more babies born, more years added to the life span and more people looking for more and better medical care will require increased supplies of doctors?

In the past ten years, the AMA—working with the Association of American Medical Colleges—has aided in the establishment of five new medical schools. It is working actively to establish still more, as rapidly as qualified universities can secure facilities and organize staffs.

Established medical schools are being encouraged to expand.

To induce qualified young people to undertake the necessarily long and arduous study of medicine, the AMA:

- **has appointed a special committee to set up an AMA-sponsored scholarship program to help promising medical students.
- **provides such "recruitment" materials as motion pictures, exhibits information literature—for the use of students, faculty advisors, and medical representatives. Many local medical societies are particularly active in medical-career programs, at both high school and college levels.

Since the earliest days of medicine, physicians have recognized their obligation to pass their medical knowledge and skills on to younger men . . . to help each new generation carry medical knowledge on to new frontiers. Physicians are doing this today through their national organization, the AMA, through their local medical societies—and as individuals: *of all the physicians teaching in medical schools, nearly half give their services without pay.* This is in addition to regular monetary contributions to schools by physicians (three million dollars in 1958 alone).

What is the Medical Profession Doing to Help Solve the Health Problems of the Aged?

Do you point out that human beings start aging from the moment they're born. So in their day-to-day practice, physicians become uniquely familiar with the process of aging.

No group is more intimately concerned with those problems than the members of the medical profession. Nor, in all likelihood, has any group devoted more study to the aging process or worked harder to find solutions to the many problems that accompany it.

The one thing that stands out in any study of the aged is that their problems are far broader than those of health alone. The aged have special needs in the field of housing, in recreation, in finding acceptance and understanding within the community, in the effort to be useful, in the preparation for retirement.

What Members of the Medical Profession Are Doing

Sustained progress is now being made under the present system of health care in meeting the complex problems of our 15 million older Americans. The more than 177,000 physicians of the American Medical Association are dedicated to helping maintain that progress and accelerate it.

They have been busy with such programs as these:

1. Finding out the facts on the problems of the aged—through regional conferences and local studies.
2. Campaigning to improve state and local assistance programs for the needy.
3. Leading community drives for construction of additional facilities to care for the aged.
4. Promoting health maintenance programs.
5. Developing rehabilitative services.
6. Pushing such plans as those which permit the sick or older person—or one who is frail—to be cared for at home.
7. Encouraging the increased use of such techniques as progressive patient care in hospitals.
8. Cataloguing the medical and social services available to the aging and making this information known.
9. Looking for ways to make more community facilities available to groups of our older people.

And ever since the American Medical Association was founded, its member physicians have been encouraged to make medical service available to all regardless of ability.

This is the healthiest nation in the world's history. It became the healthiest because the health professions were able to work in freedom; because private citizens, working voluntarily together, shared a sense of responsibility within their communities; and because health insurance was readily available to those who wanted it.

This combination is a proved quantity. It has worked in the past, and it is working now.

The medical profession does not contend that every problem of providing good health care to the aged has been perfectly solved. But it does believe that these problems *can* be solved and *will* be solved and *are being* solved in an effective and orderly fashion.

Minnesota Blue Shield

Minnesota Blue Shield opened enrollment in its Senior Citizen Plan during the month of October, offering medical-surgical coverage for persons 65 and over, Dr. Richard R. Cranmer, executive director of the medical-care plan, announced.

The last previous enrollment period was held from May 2 through June 30, 1960.

At a cost of $2.95 per month, benefits for 120 days of in-hospital medical care are provided under the Senior Citizen Plan, as well as the full range of Blue Shield surgical coverage. Electroshock therapy, X-ray treatment for specific conditions and certain anesthesia services and endoscopic examinations are also included.

The contract also provides coverage for diagnostic X-ray and laboratory services, whether performed in the doctor's office, patient's home, or the out-patient department of the hospital.

Dr. Cranmer expressed the hope that participating doctors will assume "an active role in bringing the benefits of the Senior Citizen Plan to the attention of patients who are over 65."

"It is particularly important to do so at this time," he continued. "We have already seen government entry into this field and we can expect increased efforts at the next congressional session to broaden the scope of this coverage.

"It is, therefore, important," Dr. Cranmer added, "that those who believe in the voluntary prepayment philosophy should strongly support the Blue Shield plan for senior citizens of this state."

Dr. Cranmer said participating physicians will receive application blanks for the Senior Citizen Plan and said he hoped they would display these in their waiting rooms, as so many did during the last enrollment period.

Members of the Minnesota State Pharmaceutical Association will again make applications available in drug stores throughout the state, as they also did during the May-June enrollment.

Advertising messages will stress the fact that applications may be obtained at doctors' offices or drug stores.

Endorsement of Minnesota Blue Shield by doctors to their patients has, over the years, proven one of the most effective means of expanding Blue Shield coverage throughout the community.

The doctor's effectiveness in this regard is due to the position of respect and authority which he enjoys in his dealings with patients, as well as the frequent opportunities presented him for discussing a health care plan with them.

It is important, therefore, that doctors take advantage of their position to point out the superior features of the Minnesota Blue Shield program.

In doing so, they will help maintain the community-wide coverage which has been a fundamental part of the Blue Shield philosophy, that of offering broad coverage to as many citizens as possible, the old and the young, the sick and the healthy. This is the philosophy which sets Blue Shield apart from private insurance plans.

The contribution by doctors toward the expansion of Blue Shield in their communities was vividly demonstrated during the recent enrollment period for Minnesota Blue Shield's Senior Citizens Plan. Application blanks for this plan were displayed in an attractive holder in doctors' offices, as well as in drug stores, and the response from these applications was most satisfactory.

This offering of the Senior Citizens Plan applications in doctors' offices also helped to emphasize the medical profession's participation in Blue Shield, as the plan "your doctor recommends."

Following the successful distribution of these forms through doctors' offices, applications for the Minnesota Blue Shield standard non-group contracts for those under 65 are being sent to doctors for convenient display in the same holder.

In addition, an attractive easel-back display poster, reminding patients to "Be Sure It's Blue Shield . . . Ask Your Family Doctor" is being sent each participating doctor for placing in his waiting room.

Besides these specific types of endorsement, doctors often have opportunities for discussing the Blue Shield plans before various groups in their city or town. They often have, in the past, been generous with their time in making such appearances before groups.

In continuing to do so, they make a valuable contribution to the health economy of their areas and help reaffirm the principle that voluntary health plans are a far better solution to the problem of health care coverage than any government-administered method.

Minnesota Blue Shield headquarters will gladly assist any doctor in these presentations by supplying him with data and background information for his use.

The value of these personal presentations by doctors need hardly be stressed. Just as the medical profession's courageous establishment of the Blue Shield idea twenty years ago met the challenges of the time, so also today the continued support of the Blue Shield program by participating doctors is by far the strongest bulwark against pressures for government controlled health insurance.

Prepaid medical care is a proven, workable idea and is definitely here to stay. Also, it will remain on a voluntary basis if the public fully understands the advantages of this type of coverage over tax-paid, government intervention in this field.

Blood pressure that goes up with stress often comes down with SERPASIL®

(reserpine CIBA)

One reason that many cases of hypertension respond to Serpasil is that many cases are associated with stress. Stress situations produce stimuli which pass through the sympathetic nerves, constricting blood vessels, and increasing heart rate. Hyperactivity of the sympathetic nervous system may elevate blood pressure; if prolonged, this may produce frank hypertension. By blocking the flow of excessive stimuli to the sympathetic nervous system, Serpasil guards against stress-induced vasoconstriction, brings blood pressure down slowly and gently.

In mild to moderate hypertension, Serpasil is basic therapy, effective alone "... in about 70 per cent of cases..."*

In severe hypertension, Serpasil is valuable as a primer. By adjusting the patient to the physiologic setting of lower pressure, it smooths the way for more potent antihypertensives.

In all grades of hypertension, Serpasil may be used as a background agent. By permitting lower dosage of more potent antihypertensives, Serpasil minimizes the incidence and severity of their side effects.

In Memoriam

HENDRIE W. GRANT

Dr. Hendrie W. Grant, St. Paul physician and surgeon for forty years, died August 5, 1960. He was sixty-six years of age at the time of his death.

Doctor Grant was born in Maine, where he attended the Calais High School. He graduated from Bowdoin College and Medical School at Brunswick, Maine, in 1920. He established a practice in St. Paul in 1920, continuing his graduate studies in ophthalmology at the University of Minnesota until 1923. He studied in Vienna in 1925 and 1926.

For twenty-five years, Doctor Grant had been a member of the staff at the University of Minnesota Medical School. He was also a staff member at Miller and University Hospitals. He served with the U. S. Army during World War I.

Doctor Grant was a member of the Ramsey County Medical Society; Minnesota State Medical Association; American Medical Association; Minnesota Academy of Ophthalmology, and Pan American Society.

He is survived by his wife, Elizabeth; a son, Hendrie J.; a daughter, Elizabeth Thorne, all of St. Paul.

FORDYCE RUSSELL HEILMAN

Dr. Fordyce R. Heilman, Mayo Clinic, died August 16, 1960. He was fifty-five years of age at the time of his death.

Doctor Heilman was born in Austin, Minnesota, June 16, 1905, and attended the elementary schools in Austin and Fargo, North Dakota. In 1923, he became a student in the North Dakota Agricultural College. He remained there until 1926, when he went to Northwestern University, where he obtained the degree of Bachelor of Science in 1930 and that of Doctor of Medicine in 1931.

He came to Rochester on July 1, 1932, as a fellow in surgery of the Mayo Foundation. On April 1, 1935, he was appointed a first assistant in experimental bacteriology in the Mayo Foundation, and in 1938 he received the degree of Master of Science in bacteriology from the University of Minnesota.

Doctor Heilman was appointed to the staff of the Mayo Clinic in 1939, as a consultant in the Section of Bacteriology. He became head of this section on October 1, 1944.

Doctor Heilman was appointed an instructor in bacteriology in the Mayo Foundation, Graduate School in 1939 and was advanced to assistant professor in 1941, associate professor in 1945, and professor in 1946.

He was made a charter fellow of the American Academy of Microbiology in 1957 in recognition of his position as "distinguished in the field of microbiology, with wide training and experience."

Doctor Heilman was a fellow of the American Medical Association and the American Public Health Association, a member of the Zumbro Valley Medical Society, Minnesota State Medical Association, American Medical Association, Society of American Bacteriologists, American Association for the Advancement of Science, American Society of Clinical Pathologists, American Association for Cancer Research, Society for Experimental Biology and Medicine, Society for General Microbiology, New York Academy of Sciences, Society of Sigma Xi, Alpha Omega Alpha honor society, and Phi Rho Sigma professional medical fraternity.

Survivors include a brother, Dr. Charles Heilman, Fargo, North Dakota; and a sister, Mrs. R. G. Brakke, Moorhead, Minnesota.

Dr. E. A. Kilbride, Worthington, recently resumed his practice of medicine in that city. Doctor Kilbride had been recuperating from surgery since February, 1959.

* * *

Dr. R. D. Hanover and **Dr. C. B. Will** have announced the addition of **Dr. George M. Crow** to their practice of medicine in International Falls. Doctor Crow was recently discharged from army service.

* * *

A former fellow in Otolaryngology and Rhinology in the Mayo Foundation has left that position to open a practice in Minneapolis, Minnesota. **Dr. Joseph W. Teynor** left Rochester in July.

* * *

A partner of the New London Clinic, **Dr. Wendell Ford**, left September 1 with his family for Hermiston, Oregon. As yet, no physician has been engaged to fill Doctor Ford's position at the Clinic.

* * *

On September 15, 1960, **Dr. Charles W. Mayo**, Rochester, received the 1960 Minnesota Distinguished Citizen Award given annually by the Minnesota Chapter of the Public Relations Society of America. Doctor Mayo's selection was based mainly on the contribution he has made to Minnesota in activities outside his regular profession.

* * *

The St. Luke's Hospital Educational Memorial Foundation of Duluth sponsored its second Medical Education Day recently. On the faculty for the day were **Dr. Arnold Kremen**, Minneapolis; **Dr. Claude Hitchcock**, Minneapolis; **Dr. George W. Janda**, Minneapolis; and **Dr. Donald Lannin**, Minneapolis. The program included discussions in nine specialty fields and a panel discussion on "New Concepts in Cancer Therapy."

* * *

Dr. Edward M. Litin was a guest speaker at the annual meeting of the West Virginia State Medical Association held at the Greenbrier Hotel, White Sulphur Springs, West Virginia. Doctor Litin spoke on "Problems of Adolescence" and "Emotional Aspects of Physical Handicaps."

* * *

St. Mary's Hospital, Minneapolis, Minnesota, has received approval from the Residency Review Committee for a three-year residency in obstetrics and gynecology. **Dr. Leonard Lang** is Chief of the Service and **Dr. Richard L. Jackson**, Director of Residency Training in Obstetrics and Gynecology.

* * *

Physicians of the Warren Clinic, **Dr. C. H. Holmstrom** and **Dr. E. E. Pumala**, have moved into their new clinic building constructed on the corner of Main Street and Park Avenue in Warren. The building is equipped to take care of five doctors in addition to clinical laboratories, x-ray and other necessary appurtenances.

* * *

Dr. E. O. Thorsgaard, Thief River Falls, was elected president of the Northwestern Hospital Medical Staff for 1960-61 at an organizational meeting at the Hospital. Doctor Thorsgaard, vice president of the group last year, succeeds **Dr. H. N. Boroson** who was elected Secretary-Treasurer. Vice President of the staff for the coming year will be **Dr. M. A. Mochal.**

* * *

Dr. Charles Vandersluis, formerly of Warren, has opened his own practice of medicine in Minneota. No replacement has been secured as yet for his position in Warren.

* * *

Rochester physician, **Dr. L. B. Woolner** and his family, have returned from an eight-week trip to Europe. Doctor Woolner attended the Fourth International Goiter Congress and the International Academy of Pathology both in London.

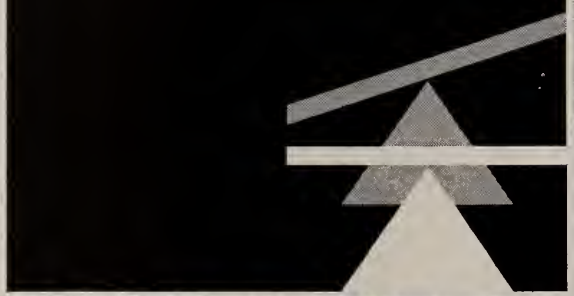
* * *

The Stoughton Avenue Clinic in Chaska has announced the appointment of **Dr. Gerald Nelson** as an associate of **Dr. G. T. Schimelpfenig** in the practice of medicine. Doctor Nelson is a graduate of the University of Minnesota.

* * *

Dr. Gershom Thompson, head of the Section of Urology at the Mayo Clinic, took over the presidency of the U. S. Section of the International College of Surgeons at the group's annual meeting in Winnipeg, Canada, on September 28 and 29. Dr. Thompson, elected to the post recently, replaced Dr. Edward L. Compere of Chicago. His term is for one year.

* * *



Dr. W. D. Brown, Jr., Minneapolis, has joined the practice of medicine with his father, **Dr. W. D. Brown, Sr.** Dr. Brown, Jr., makes the third generation of the Brown family who have practiced the profession of medicine.

* * *

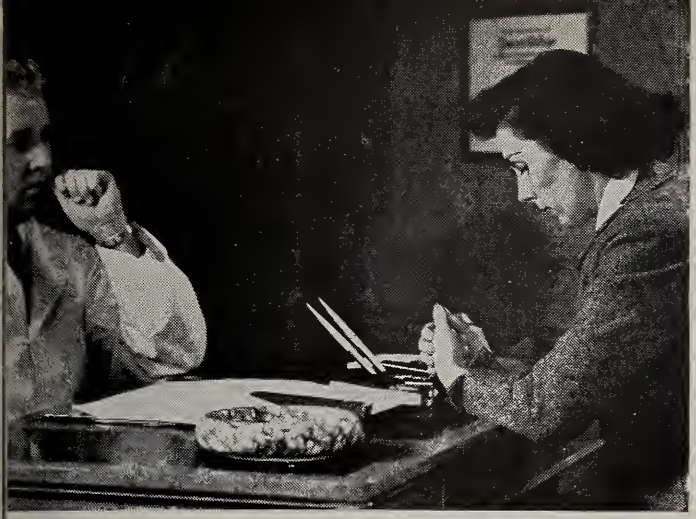
The French National Society of Physical Medicine has elected **Dr. Frank H. Krusen**, Rochester, as an honorary member of the group. Doctor Krusen has served as president of every major national and international organization devoted to his special field of medicine. Doctor Krusen served as president of the Third International Congress of Physical Medicine and Rehabilitation at Washington, D. C.

in rheumatic disorders

whenever aspirin proves inadequate

Sterazolidin®

brand of prednisone-phenylbutazone



Even in the more transient rheumatic disorders, an anti-inflammatory effect more potent than that provided by aspirin is often desirable to hasten recovery and get the patient back to work.
By combining the anti-inflammatory action of prednisone and phenylbutazone, Sterazolidin brings about exceptionally rapid resolution of inflammation with relief of symptoms and restoration of function.
Since Sterazolidin is effective in low dosage, the possibility of significant hypercortisonism, even in long-term therapy, is substantially reduced.

Availability: Each Sterazolidin® capsule contains prednisone 1.25 mg.; Butazolidin®, brand of phenylbutazone, 50 mg.; dried aluminum hydroxide gel 100 mg.; magnesium trisilicate 150 mg.; and homatropine methylbromide 1.25 mg. Bottles of 100 capsules.

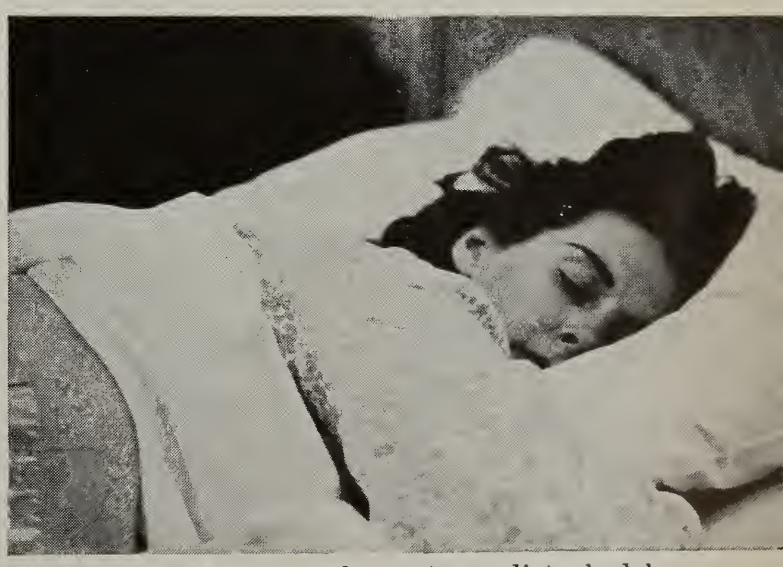
Geigy, Ardsley, New York

Geigy

165-60

The physician listens to a tense, nervous patient discuss her emotional problems. To help her, he prescribes Meprospan® (400 mg.), the only continuous-release form of meprobamate.

The patient takes one Meprospan-400 capsule at breakfast. She has been suffering from recurring states of anxiety which have no organic etiology.



She stays calm while on Meprospan, even under the pressure of busy, crowded supermarket shopping. And she is not likely to experience any autonomic side reactions, sleepiness or other discomfort.

She takes another capsule of Meprospan-400 with her evening meal. She has enjoyed sustained tranquilization all day—and has had no between-dose letdowns. Now she can enjoy sustained tranquilization all through the night.

Relaxed, alert, attentive . . . she is able to listen carefully to P.T.A. proposals. For Meprospan does not affect either her mental or her physical efficiency.

Peacefully asleep . . . she rests, undisturbed by nervousness or tension. (Samples and literature on Meprospan available from Wallace Laboratories, Cranbury, N. J.)

Dr. Edwin Tanquist, Jr., has joined his father **Dr. E. J. Tanquist** in the practice of medicine in Alexandria. Dr. Tanquist, Jr., formerly practiced in Panama. He is a graduate of the University of Minnesota.

* * *

The Pine County Board of Commissioners has appointed **Dr. E. G. Hubin,** Sandstone, to the post of Pine County Coroner.

* * *

Among doctors participating in the program of the Third International Congress of Physical Medicine in Washington, D.C., were **Dr. Frederick J. Kottke,** Minneapolis; **Dr. Earl C. Elkins,** Mayo Clinic; **Dr. Miland E. Knapp,** Minneapolis; and **Dr. Paul M. Ellwood, Jr.,** Minneapolis.

* * *

"Electroencephalography in Anesthesiology" was published by Charles C Thomas recently. One of the authors is **Dr. Albert Faulconer, Jr.,** head of the Section of Anesthesiology at the Mayo Clinic. The book deals with the application of what is learned from measurements and recordings of the electrical energy of the brain to the state of anesthesia.

* * *

Former Evansville physician, **Dr. Erling Ostergaard,** has moved to Chinle, Arizona. He will work with the Indians at the Rock Point Mission there.

* * *

The August 8 issue of the *Tyler Journal* carried an editorial devoted to the fiftieth anniversary of **Dr. A. L. Vadheim's** medical practice in that community and surrounding area. The people of Tyler and area sponsored a special Dr. A. L. Vadheim appreciation day on August 10, 1953, in recognition of his forty-three years of service. Doctor Vadheim now resides in Brookings, S. D.

* * *

Harmony, Minnesota, has a new physician. He is **Dr. Albert A. Bodaski,** formerly of Tyler, Minnesota. where he had practiced medicine for the past eight years. Prior to his stay in Tyler, Doctor Bodaski practiced in Montgomery, Minnesota. He is a graduate of the University of Minnesota.

* * *

Dr. E. J. Huenekens, vice president of the Minneapolis Welfare Board, has submitted his resignation. He was a member of the Board of Welfare for fifteen years.

* * *

Appointment of **Dr. E. C. Clark,** Mayo Clinic, to the Board of Public Health and Welfare of Rochester has

adult stable diabetics and a significant number of sulfonylurea failures respond to

DBI

trademark, brand of Phenformin HCl

adult stable diabetes

"In our experience the action of DBI on the adult stable type of diabetes is impressive . . . **88% were well controlled by DBI."**[1]

"Most mild diabetic patients were well controlled on a biguanide compound [DBI], and such control was occasionally superior to that of insulin. This was true regardless of age, duration of diabetes, or response to tolbutamide."[2]

"DBI has been able to replace insulin or other hypoglycemic agents with desirable regulation of the diabetes when it is used in conjunction with diet in the management of adult and otherwise stable diabetes."[3]

sulfonylurea failures

Among those diabetics who responded to tolbutamide initially and became secondary failures **DBI "gave a satisfactory response in 55%."**[4]

"DBI is capable of restoring control in a considerable portion of patients in whom sulfonylurea compounds have failed, either primarily or secondarily."[5]

"All twelve secondary tolbutamide failures have done well on DBI."[6]

"34 out of 59 sulfonylurea primary failures were successfully treated with DBI."[7]

been announced. It was also announced that the Mayor is ready to appoint another physician to the Board when such action becomes authorized by ordinance.

* * *

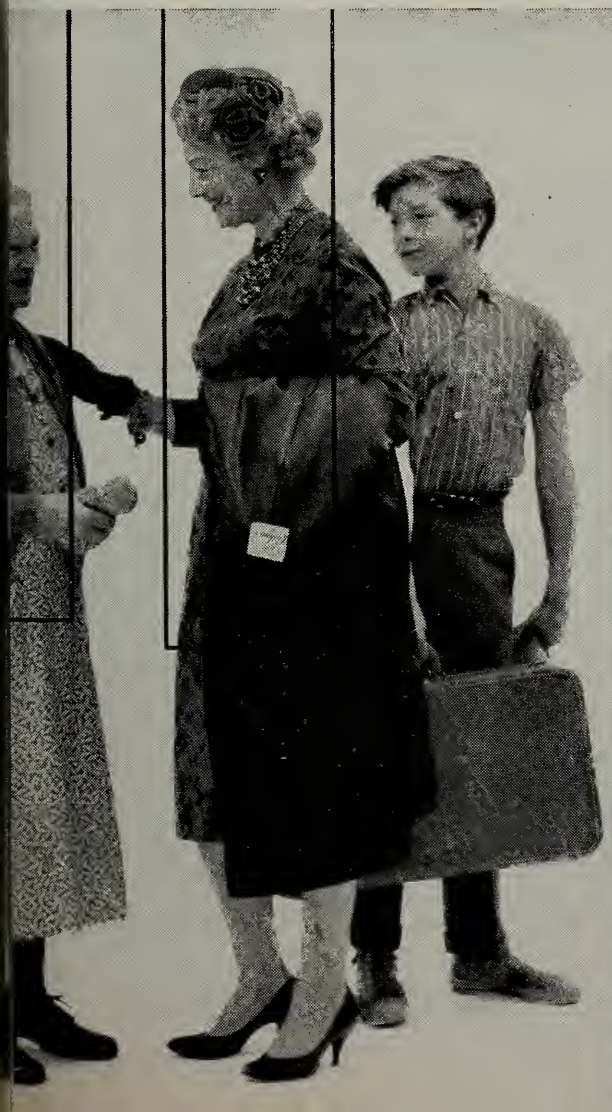
Dr. N. E. A. Leppo, Duluth pediatrician, recently returned from a three-week trip to South America to attend the fiftieth anniversary meeting of the Brazilian Pediatric Society in Rio de Janeiro and the Pan American Pediatric Congress in Caracas, Venezuela. He also visited his brother who is the Finnish Ambassador in Argentina.

* * *

Chaska and the surrounding area now have the services of an additional physician. **Dr. Patrick J. Adams** is now an associate of **Dr. C. R. Heinzerling.** Doctor Adams is a graduate of Loyola University in Chicago.

* * *

Dr. Robert R. Kundel, formerly of Ely, has accepted a radiology residency with the Veterans Administration Hospital and the University of Minnesota in Minneapolis. The residency rotates among Veterans Administration, University, Minneapolis General, and Ancker Hospitals.



Dr. Gordon R. Kamman, St. Paul, attended a staff meeting of the Bangkok Sanitarium and Hospital in Bangkok, Thailand, on August 23. While in Bangkok, Dr. Kamman met and visited with **Dr. Tom Dooley** who, because of the unsettled conditions in Laos, came over to Bangkok.

* * *

Among those honored at the First Awards Convocation at the Mayo Foundation were **Dr. Juergen E. Thomas,** Mayo Clinic, winner of the Edward John Noble Foundation Award, for the display and development of leadership; and **Dr. Louis A. Buie, Jr.,** Mayo Clinic, recipient of the Howard K. Gray Travel Award for 1961.

* * *

Dr. Earl E. Christenson, the fourth recipient of the Rural Medical Scholarship sponsored annually by the Minnesota State Medical Association, began his practice of medicine in Clinton, Minnesota, on July 5, following the completion of his internship at Bethesda Hospital in St. Paul.

New meal-in-a-glass dietary food with

pre-measured calories gives physicians a new to

patients a new incentive in weight control

Announcing

QUOTA

maintains nutrition on 900 calories—QUOTA supplies the daily R.D.A.* of protein (70 Gm. per one-half pound), plus carbohydrate and fat, vitamins and minerals to fulfill established M.D.R.

satisfies hunger—QUOTA is a high-satiety food; patients may be allowed to eat celery, radishes, green pepper and similar low-calorie "snacks" at mealtime or between meals, if they wish.

EASY TO PREPARE—Patient simply mixes contents of QUOTA can with 1 qt. of water in a shaker or bowl

A WHOLE DAY'S SUPPLY may be made at once and stored in covered container in refrigerator

*Recommended Dietary Allowance established by the National Research Council, Publication 589, National Academy of Sciences, Washington, D.C., 1958.

DOCTORS CHARGED WITH LOWER HOSPITAL COST RESPONSIBILITY

A study committee appointed by the New Jersey Commissioner of Insurance to investigate the rising costs of Blue Cross rates in that state, has placed the responsibility for reducing the cost of hospital care directly on the doctor.

The Committee, in its final report, presented the following analysis of New Jersey hospital charges from 1953 to 1958.

"Hotel" costs—food, housekeeping, personnel and administration—accounted for a 7.8 per cent increase in the total per diem cost. During the same period, medical care costs—including laboratory procedures, house staff and nurses' salaries, drugs and equipment—accounted for a 24.6 per cent increase. In addition, there was a utilization rate increase of 12.1 per cent.

Doctors Select Services

"The major cost increases have been in the area of medical and professional care", the Committee stated. It was noted that physicians admit patients to the hospital, determine how long they should stay, decide what services must be available, and the extent of their use. Therefore, the Committee said, it is "amplifying the call to the medical profession for cooperation in attempting to cut Blue Cross rises."

"Blue Cross itself acts only as a middleman in passing hospital costs on to the consumer," according to the report. And it certainly exercises "no direct control over hospital expenditures."

TAX STATUS OF MEDICALLY PRESCRIBED TRAVEL UPHELD

The Tax Courts have upheld a 1954 Congressional amendment with regard to the tax status of doctor-prescribed travel to a resort. The case considered by the court involved a Brooklyn wage earner who appeared before the Court in his own behalf and argued that the $493.50 spent on a nine-day trip to Bermuda by himself and his wife was a medical expense. The Court found that the $217.80 for round-trip transportation of husband and wife was deductible, but the outlay for hotel and meals was not. When Congress amended the tax laws in 1954, the Court explained, it made it clear that *transportation alone,* for the patient and any necessary aide, was deductible in cases where travel was medically indicated and prescribed.

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

The Influence of Ethanol on Serum Cholesterol Concentration

FRANCISCO GRANDE
DONALD S. AMATUZIO
Minneapolis, Minnesota

BECAUSE of the correlation between serum cholesterol concentration and incidence of coronary infarction[1,2] there is great interest in studying the factors affecting the cholesterol levels. There is good evidence at the present[3-5] that the diet, and particularly the amount and kind of dietary fat, has a significant influence on serum cholesterol level in man. Other dietary components may have also some effect upon serum cholesterol concentration, as indicated by experiments in animals, but the changes in blood lipids are produced only under such extreme dietary changes that it is doubtful that the results are relevant to explain the cholesterol differences between men subsisting on the usual human diets. Experiments in man have shown[6] that changes in the nature of dietary carbohydrates produces significant but small changes of serum cholesterol concentration.

In spite of the fact that alcohol is so widely used, only limited attention has been given to the study of its effects on serum cholesterol concentration. The old concept that arteriosclerosis is a direct outcome of excessive alcohol intake is not supported by the more recent experience. In fact the autopsy data from alcoholic persons indicate that heavy alcoholics are remarkably free from atherosclerosis, and some observations have been interpreted as showing that alcohol has a protective effect in decreasing the development of atherosclerotic lesions[7,8]. The autopsy data, however, are controversial and other explanations are possible. Wilens,[9] noting the dietary intake of alcoholics, concluded that alcohol itself does not protect the arterial system from the development of atherosclerosic lesions; and the relative absence of atherosclerosis in the alcohol subjects could be explained by their decreased food intake.

From the Jay Phillips Research Laboratory, Mount Sinai Hospital, and the Departments of Physiological Hygiene and Medicine of the University of Minnesota, Minneapolis, Minnesota. Supported by Grants from the John A. Hartford Foundation, the Mount Sinai Hospital Research Fund, and the Minnesota Heart Association.

On the other hand Kimura[10] has recently reported that marked atherosclerosis is more frequently found in the autopsies of men who habitually drank and smoked cigarettes than in autopsies of men who indulged in neither. Gertler and his collaborators,[11] in a study of young victims of coronary infarction, concluded that they had a lower alcohol intake but had used more concentrated alcohol beverages than a control group of healthy men. Spain and Bradess[12] reported on a group of chronic alcoholics in which 7 per cent of the men died of coronary occlusion. The male chronic alcoholics of their group died at the same age as the rest of the population. Alcoholism in itself did not appear to accelerate or prevent the atherogenic process in this study. Finally Jankelson and his associates[13] have observed that atherosclerosis is not less frequent among chronic alcoholics than among non-alcoholic men of comparable age.

Little attention has been given in the past to the effects of alcohol on serum cholesterol concentration in man. Hobson and his group,[14] in a study on elderly people, have reported that the average serum cholesterol concentration in heavy drinkers is lower than that of abstainers or moderate drinkers. These observations, however, do not agree with the older observation by Ducceschi and Barilari[15] who found higher cholesterol values in habitual drinkers of alcoholic beverages than in all abstainers of comparable age. The recent studies by Jankelson et al,[13] show no difference in serum cholesterol concentration between chronic alcoholics and non-alcoholics.

Experimental work in animals has given conflicting results. In 1914 Ducceschi[16] reported an increase of serum cholesterol concentration in dogs given high doses of alcohol for a few days. Eberhard (1936) found that administration of alcohol increases serum cholesterol levels and reduces the amount of lipid deposited in the arteries of the rabbit.[17] These observations, however, were not confirmed by Feller and Huff.[18] Morgan and his co-workers have found that the increase in serum cholesterol of female hamsters on a cholesterol-containing diet was greater in the animals drinking water than in the animals given wine.[19] In contrast, Gottlieb and his collaborators[20] published an extensive study of the effects of ethanol on serum cholesterol concentration in the rat. It was found that administration of 20 per cent ethanol to rats on a diet containing 1 per cent cholesterol and 0.3 per cent of cholic acid resulted in higher serum cholesterol levels than those observed in rats on the same diet, without alcohol. The animals receiving alcohol also showed a more extensive vascular sudanophilia than the rats fed the atherogenic diet with water. When the ethanol was given to rats receiving a diet free of cholesterol and of cholic acid, the serum cholesterol level was slightly higher than in the animals on the same diet with water.

The effect of alcohol ingestion on serum cholesterol concentration and development of experimental athersclerosis in chicken has been studied recently by Nikkila and Ollila.[21] Cockerels fed different diets showed significantly higher serum cholesterol and phospholipids when 7 per cent ethanol was given as drinking fluid, than control animals on the same diets but drinking water. No protective effect of alcohol against the atherosclerosis-inducing power of hypercholesterolemia was found in these experiments.

From the preceding review of the literature it is clear that more information is required to establish the influence of alcohol on serum cholesterol concentration, and its possible influence on the development of the atherosclerotic lesions. In this laboratory we have been interested in the study of the effect of ethanol on serum cholesterol concentration as a result of the observation by Amatuzio and Hay in 1958,[22] that alcohol increases the concentration of cholesterol and other serum lipids in hyperlipemic individuals. Accordingly, controlled dietary experiments were made in dogs and normal men[23,24] in an attempt to establish the effect of ethanol administration on the concentration of serum cholesterol. The results of these experiments show that alcohol increases serum cholesterol concentration in the dog and in man, but that the effect in man is less marked than in the dog.

The Effect of Ethanol on Serum Cholesterol Concentration in Dogs.—Normal male dogs were used in these experiments. The animals were fed a basic low-fat commercial dog food of low cholesterol content (18 mg. of Lieberman Burchard reacting material per 100 g.). This diet was mixed with fat to make the proportion of fat calories up to 40 per cent of the total. The animals were fed at libitum, and their weight

was determined each week. Alcohol was administered daily by stomach tube at the amount of 1.65 g. of ethanol per kg. of body weight (1 ml. of 95 per cent alcohol per pound of body weight). The experiments were done following a switch-back reversal design. Alcohol was given to only half of the dogs during the first two-week period and to the other half during the second period. The duration of the experimental periods was two weeks. The details of the methods used have been described elsewhere.[24]

Administration of alcohol at the amount of 1.65 g./kg. per day produced in all the dogs a significant increase of serum cholesterol concentration which reached a maximum after two weeks of treatment. The increase of serum cholesterol concentration was also studied in dogs subsiding on the low fat diet (4 per cent of fat calories) and in dogs subsisting on high fat diets (40 per cent of fat calories). The fats used for supplementing the diet were either lard or sunflower oil.

The results of three groups of experiments are summarized in Table I.

It is evident that administration of ethanol produced a significant increase of serum cholesterol concentration after two weeks of daily administration. The increase observed in the animals receiving the high-fat diets appears to be higher than that observed in the animals on the low-fat diet. However, statistical analysis of an experiment comparing the same animals on both the low and the high-fat diet showed that the difference is not statistically significant. No significant difference exists between the responses to ethanol observed on the high-fat diets of either lard (low in poly-unsaturated fatty acids) or sunflower oil (rich in poly-unsaturated fatty acids). It should be noticed that the effects of dietary fat and alcohol on serum cholesterol concentration in the dog are additive. An increase of serum cholesterol was observed when the dogs were changed from a low-fat diet to a high-fat diet, and a greater increase was produced when the alcohol was given with the high-fat diet.

On discontinuing the administration of alcohol, the serum cholesterol concentration decreased and reached the pre-alcohol level in about two weeks. On the other hand if the alcohol administration continues, the serum cholesterol concentration is maintained approximately at the same level as observed at the end of the first two weeks of alcohol administration. Dogs maintained in this laboratory for several months with daily administration of alcohol and high fat diet (lard) continued to show the same high levels of serum cholesterol as observed at the end of the initial two-week period.

The cholesterol response to ethanol administration is again observed if a second period of alcohol administration is started after weeks or months without alcohol. An experiment done with a group of five dogs showed that the cholesterol response to ethanol after a period of several weeks without alcohol was statistically not different from that observed after the first alcohol administration.

Experiments in this laboratory have shown that the elevation of serum cholesterol produced in the dog by ethanol cannot be prevented by administration of nicotinic acid.[25] In fact the cholesterol increase produced in six dogs by the administration of 1.65 g. of ethanol/kg. per day for two weeks, was statistically not different from the increase observed in the same dogs when the alcohol was administered when the animals were receiving 1.2 g. of nicotinic acid per day (mean weight of the dogs 17.5 kg.).

THE EFFECT OF ETHANOL (1.65 g./kg./day, FOR TWO WEEKS) ON SERUM CHOLESTROL CONCENTRATION IN THE DOG

Exp.	No. of Dogs	Diet	Serum Total, Cholesterol, mg./100 ml. No Alcohol	Alcohol	Difference	P
I	8	Low Fat	136±11.7	188±14.8	52±8.2	=0.0004
II	24	High Fat (lard)	200± 9.5	275±10.8	75±6.6	<0.0001
III	6	High Fat (Sunflower oil)	192±17.6	281±19.7	89±6.0	<0.0001

Values are means and Standard errors of the means.

TABLE I.

The Effect of Ethanol on Serum Cholesterol Concentration in Normal Men.—Two experiments were performed on normal men—inmates in the Minnesota State Prison in Stillwater, Minnesota. These men subsisted on a normal diet containing approximately 38 per cent of fat calories. The technical details have been described elsewhere.[24] Fifty-nine men participated in the first experiment in which 3 ounces of 100-proof whiskey were given per day. The effect of the whiskey was compared with that of an isocaloric amount of syrup. A switch-back design was followed: half of the men received the whiskey for a period of three weeks while the rest of the men received the syrup supplement. After three weeks the treatments were reversed. Body weight determined weekly was constant. No significance differences were observed at the end of three weeks, between the cholesterol levels on alcohol and on syrup.

A second experiment with a larger daily alcoholic intake was performed with a group of fourteen men. Seven men received for three weeks a daily supplement of 9 ounces of 100-proof whiskey divided into three doses of 2, 3, and 4 ounces, respectively. The other seven men were given instead an isocaloric amount of syrup and the experimental reverse type design was followed as in the previous experiment. A small but statistically significant increase of serum cholesterol concentration (18 mg./100 ml.) was observed in this experiment, which indicates that this high amount of alcohol produces an elevation of serum cholesterol in man. However, it is less pronounced than that observed in the dog. The amount of ethanol ingested by the fourteen men in this experiment was on the average 1.36 g./kg. per day.

Analysis of the cholesterol changes observed in this experiment indicates a significant correlation between the response to ethanol and the initial serum cholesterol level of the subjects. The men having higher serum cholesterol concentration during the control period showed also a greater cholesterol increase with the administration of alcohol.

The Effect of Ethanol on Serum Cholesterol in Hyperlipemic Men.—Studies made in this laboratory[22] have shown that the fasting serum of patients with essential hyperlipemia, becomes clear with a decrease of the concentration of the different lipid fractions, when dairy foods are eliminated from their diets. This effect failed to be produced in some of the subjects who habitually ingested a moderate amount of alcoholic beverages. A systematic study of the serum lipids of these patients demonstrated that the serum became clear when the alcohol ingestion was discontinued. The addition of alcohol at the dose of ½ to 3 oz. of ethanol per day for one to three weeks while subsisting on an isocaloric diet devoid of dairy fats produced turbidity of the fasting serum with increase of the concentrations of cholesterol, total esterified fatty acids, and lipid phosphorus.

Comment

The experiments which have been summarized show that ethyl alcohol produces a very marked effect on serum cholesterol concentration in the dog. Our findings agree with the older data published by Ducceschi[16] and seem to indicate that the dog is particularly sensitive to the effect of alcohol in this respect. This fact adds an interesting data to our knowledge about the differences in lipid metabolism between different animal species.

Other authors have found increases of serum cholesterol in animals after administration of ethanol, but most of the experiments have been done while the animals were receiving diets of high cholesterol content and added with bile acids. The study by Gottlieb et al[20] is important in this respect in showing that the response of the rat's serum cholesterol to ethanol is much greater when the animal has been made hypercholesterolemic by administration of cholesterol and bile acids, than when the animal was kept on a diet devoid of cholesterol and bile acids.

There is no explanation at the present for this effect of ethanol. Ducceschi[16] stated that the effect of alcohol on serum cholesterol concentration was related to its narcotic effects but experiments performed in this laboratory with administration of the ethanol in divided doses, in order to prevent the narcotic effect, have shown that the cholesterol response is essentially the same than when the ethanol is administered in a single dose.[24]

It is known that ethanol is oxidized in the body to acetic acid and that acetic acid can be used as a precursor of cholesterol.[26,27] However, administration of acetate at a dose corresponding to the amount of ethanol given to the dogs, failed to produce any change of serum cholesterol concentration.[24]

Nikkila and Ollila[21] suggested that the effect of the alcohol may be related to the pyridine nucleo-

tides which participate in the enzyme systems involved in the synthesis of cholesterol and fatty acids and in the enzyme systems responsible for the metabolism of ethanol. This possibility, however, is not supported by our experiments with nicotinic acid and ethanol in the dog, which showed that the administration of a large dose of nicotinic acid fails to modify the effect of alcohol on serum cholesterol concentration in this animal.[25]

The effect of ethanol on the serum cholesterol concentration in normal man is certainly small, and high doses of ethanol are needed to produce an elevation of serum cholesterol which reaches statistical significance. However, the fact that such an increase is produced indicates that alcohol may be of some importance in maintaining high levels of serum cholesterol in individuals drinking large amounts of alcoholic beverages and subsisting on high-fat diets.

The fact that ethanol increases serum cholesterol (and other lipids) concentration in the serum of hyperlipemic individuals is important from the medical viewpoint and indicates that these patients should be advised against drinking alcoholic beverages. The same is true of essential hyperlipemic individuals and in subjects with high intrinsic cholesterol levels.[22,24] The results of our experiments in men indicate that these individuals should avoid drinking of alcoholic beverages, in addition to the usual dietary measures, in order to lower their serum cholesterol levels. The difference in the magnitude of the cholesterol responses to ethanol between dog and man poses an interesting problem as to the differences in cholesterol metabolism between these two species. It is hoped that a better understanding of the cause of this difference may be helpful for a better understanding of the mechanisms regulating serum cholesterol concentration. Studies in this direction are pursued at the present in this laboratory.

Summary

A review of the literature on the effects of alcohol on serum cholesterol concentration in man and different animal species has been given, as well as a summary of the experimental studies done in this laboratory on men and dogs.

The dog responds with a marked increase in serum cholesterol concentration when given alcohol at the dose of 1.65 g./kg./day. Administration of large amounts of alcohol to normal men (9 oz. of 100-proof whiskey per day) produces a small but significant increase of serum cholesterol concentration in normal men subsisting on a normal diet (about 38 per cent of fat calories).

The increase in serum cholesterol concentration produced by administration of ethanol in man is related to the intrinsic cholesterol level of the individual. Essential hyperlipemic patients respond with a very marked increase of serum cholesterol and other lipids, when given alcohol at moderate doses. The possible role of ethanol in maintaining high serum cholesterol levels in man has been discussed.

A Consideration of

REITER'S SYNDROME

and

ISADORE FISHER, M.D.
Minneapolis, Minnesota

THE PURPOSE of this paper is to present a case of psoriatic arthritis that possessed many misleading features. As will be shown in the case report, there were confusing symptoms and signs that made the consideration of related conditions necessary before the final diagnosis was made. Features of the related diseases will be enumerated in the differential diagnosis. Owing to the similarity in the clinical picture, the principal related condition to be considered was Reiter's syndrome.

From the Division of Dermatology, University of Minnesota Medical School, Minneapolis, Minnesota, Francis W. Lynch, Director.

Dr. Fisher is Attending Dermatologist, Mount Sinai Hospital, Minneapolis, Minnesota, and Attending Dermatologist, United States Veterans Hospital, Fort Snelling.

Numerous articles and case reports have appeared in the world literature since the original article was published by Reiter in 1916. The syndrome has been described in detail with the most emphasis upon the triad of symptoms: urethritis, conjunctivitis, and arthritis. These three cardinal symptoms are not always present simultaneously, and many writers believe that one or two of the components may be entirely absent. Other features have been added to the description of Reiter's syndrome and consist chiefly of cutaneous and mucous membrane lesions. Less-frequently-mentioned manifestations of Reiter's syndrome consist of polyneuritis, cardiac involvement, pleurisy, diarrhea, lymphadenopathy, fever, and loss of weight.

The diagnosis of Reiter's syndrome is often one of exclusion. Confusion may exist between this

DIFFERENTIAL DIAGNOSIS OF PSORIATIC ARTHRITIS AND REITER'S SYNDROME

	PSORIATIC ARTHRITIS	REITER'S SYNDROME
Sex	Equal in both sexes	Predominately male
Urethritis	Absent	Present—early
Conjunctivitis	Absent	Present—early
Arthritis	Worse in terminal phalanges, lumbar spine, sacroiliac	Knees, ankles, feet, sacroiliitis, shoulders, elbows, wrists, and hands
Constitutional symptoms	Minimal except for joint pain	Fever, weight loss, central nervous system and cardiovascular involvement, pleurisy and lymphadenopathy
Skin	Psoriasis-moderate Nail changes a prominent feature	Psoriasis-like involvement with most changes on genitals and extremities
Mucous Membrane	None	Usually genitals, oral mucosa
Course	Prolonged	Self-limited
Recurrences	Common	Frequent, usually with complete recovery
Histology	Parakeratosis with micro-abscesses, acanthosis, papillomatosis, clubbing of rete ridges, mild perivascular infiltrate in upper cutis	Parakeratosis, spongiosis, acanthosis, papillomatosis. Neutrophiles throughout all layers of some pustules. Heavy, acute infiltrate in corium

Allied Conditions

disease and psoriasis vulgaris with associated arthritis. Reiter's syndrome has been reported mainly in young, white, adult males, the age distribution being in the second and third decades, which is the same age group as the patients with psoriatic arthritis. There are a few isolated reports of the disease in females and children. The highest incidence is 10 per cent in women as reported by Paronen. The disease has also been reported in negroes. Reiter's syndrome is usually found in those who have not had a history of previous venereal diseases.

Paronen, as well as other writers, are of the opinion that both the dysentery and the urethritis are not causative factors in the disease, but are caused by the same etiologic agent. He stresses the factor of a more specific urethritis, pointing out that the complement fixation test for gonococci was negative in all his cases. The presence of diarrhea as a precursor in some cases and urethritis in others, suggests that there is more than one portal of entry for whatever organism causes the syndrome.

Reiter reported the isolation of a spirochete from the blood of his patient as the causative agent and termed the condition "spirochoetosis arthritica." No one else has been able to duplicate his finding of spirochetes. In Paronen's study of 344 cases, dysentery preceded the appearance of Reiter's disease in 96.4 per cent of the cases. This large series of cases was seen during the course of an epidemic of bacillary dysentery in Finland. Five of the twenty-three patients reported by Hall and Finegold had diarrhea. More frequently the history of extramarital or promiscuous sexual exposure suggest a venereal origin.

Shatin, Canizares, and Ladany in a recent paper propose the grouping of keratosis blennorrhagica with Reiter's syndrome—using modifying adjectives to indicate etiology. They would divide Reiter's syndrome into the gonococcal or the dysenteric type. Csonka, in reporting 185 consecutive cases, examined possible precipitating or predisposing factors and pointed out the relationship to previous urologic surgery. He could find no hereditary predisposition to the arthritis manifestations. There is a decided tendency for recurrences of the syndrome. Pleuropneumonia-like organisms have been suggested as the cause of Reiter's syndrome. The organism has been isolated in cultures of urethral discharge. The factor of virus etiology has not been carefully studied or eliminated.

Clinical Manifestations

One usually requires the presence of the triad of symptoms in order to make a diagnosis of Reiter's syndrome. The earliest symptom is most frequently urethritis. There may also be evidence of other urologic conditions such as prostatis, cystitis, or pyelonephritis. The urethritis is of a non-specific nature as evidenced by dysuria or frequency of urination, and purulent urethral discharge which may vary considerably in degree and duration—sometimes lasting several months. The discharge is less profuse than that seen in acute gonorrheal urethritis. It may vary from a sero-purulent to a heavy purulent or bloody secretion. The bacteriologic findings are usually negative, though the pleuropneumonia organism has been isolated from some patients.

The ocular manifestations appear within a short time after the urethritis. Conjunctivitis is the most frequent form of eye involvement and may vary greatly in its severity. It is usually bilateral, may be present only for a day, and may easily escape the patient's attention. Also reported have been cases of iritis, keratitis, corneal ulceration, and iridocyclitis.

The articular symptoms in Reiter's syndrome are the predominant ones and are the symptoms that bring the patient to the doctor. Changes come on acutely and are accompanied by a great deal of pain. In the great majority of cases, the arthritis is polyarticular involving commonly the knees, ankles, and feet. Other involved joints are the shoulders, elbows, wrists and hands singly or together. In contrast to rheumatoid arthritis, Csonka states that in Reiter's syndrome the joints of the lower limbs are affected three times as commonly as are the upper limbs. Csonka also stresses the frequent accompaniment of sacroiliitis. There may be evidence of acute periositis. The picture may resemble gonorrheal arthritis or gout. Acute arthritis in the sternal and shoulder area is often a prominent symptom.

A generalized polyarthritis that persists for a long time may develop in some cases. Tenderness over spinous processes and on motion of the spine are frequently present. Acute arthritic symptoms, involving one or two joints of the feet and clearing spontaneously in a week, may even be mistaken for gout. The majority of patients recover spontaneously and completely from one or several attacks. Residual joint damage may be found. Csonka reported more than one attack in 104 of 185 cases, and noted that with repeated attacks recovery was less complete. Fort estimates that in 20 per cent of recurrent attacks spondylitis will develop. In contrast, most reports agree that the changes in the larger joints (especially of the spin) are indistinguishable from those seen in patients with rheumatoid arthritis.

Duration of joint symptoms varies greatly. If only arthralgia is present recovery may begin in two weeks. In most cases the joints are cleared in three to eight months. Roentgen studies have shown osteoporosis and slight signs of bone destruction. Sacroiliitis is a common radiologic finding.

The prognosis for complete recovery is good and the x-ray changes are reversible. Mason and his collaborators state that "florid" periostitis is very suggestive of Reiter's syndrome and when it occurs on the plantar aspect of the calcaneum it is probably pathognomonic. Also Mason has the impression that changes of periosteal new bone in the calcaneum appear to be the only differentiating factor between Reiter's syndrome and rheumatoid arthritis.

The cutaneous manifestations of Reiter's syndrome is merely mentioned in some papers. On the other hand, M. Montgomery suggests that Reiter's syndrome be discussed as a tetrad rather than a triad of symptoms. Hall and Finegold agree that skin findings are an important part of the disease and are of considerable help in arriving

at a diagnosis. All of their cases showed some cutaneous evidence, the most frequent site of involvement being the genitalia. Hall and Finegold observed characteristic papular lesions on the prepuce or glans penis in seventeen of their twenty-three patients. The high incidence of mucocutaneous lesions is not generally appreciated. These lesions may be diagnostic and occur very frequently in the endemic (venereal) type of the disease. Montgomery and his group reported the incidence of mucocutaneous lesions in 80 per cent of their patients. Paronen, whose 344 cases were of the dysentery form, reported eighty-seven cases of penile eruptions representing 26.1 per cent of the total number of cases. The most frequent lesion appears on the penis as a perimeatal erosion or on the glans as balanitis circinata. The balanitis which is usually asymptomatic, is a papulosquamous circinate superficial process whose scales are loosely attached. These lesions are frequently seen at the corona and may involve the prepuce. Sometimes the lesions are coalescent, crusted, maculo-papules which are arranged in a serpiginous fashion. There may be small vesicles or superficial erosions. In some instances one sees a circinate, shallow erosion surrounding the urethral meatus. Ulcerative lesions may be seen on the penile shaft also.

The oral mucosa is the next most frequent site for mucocutaneous lesions. Here one may see grouped, annular erosions on the palate or buccal mucosa. They may be the residue of vesicles that rupture early to leave a relatively painless, red erosion. Some grouped vesicles strongly resemble herpetic stomatitis or erythema multiforme. Similar lesions may appear on the tongue, pillars and pharynx. Montgomery observed extragenital mucous membrane lesions in fourteen of his thirty-eight patients. The typical lesions are described as "dark red, slightly elevated, painless papules." Some lesions are to be found on the tongue as well. The nasal mucosa and perianal areas may also be involved.

The remaining cutaneous lesions of Reiter's syndrome are seen as sharply delimited, keratotic or parakeratotic plaques which are often confusedly referred to as keratodermia blennorrhagica. These lesions probably begin as vesico-papules that increase in size, become crusted and hyperkeratotic. They may be seen scattered over the glabrous skin, but most frequently involved sites are the palms and soles. There the papulo-vesicular lesions are covered with heavy crusts that interfere greatly with function. The lesions on the feet are located on the weight-bearing portion. The papulo-vesicles may be firm to palpation, seemingly solid. The skin between the toes may become macerated. There may be thick crust formation extending to the dorsum of the feet, even to appearing on the hands and arms. Crusts have been described in the scalp, about the hair margin and in the peri-umbilical area. External otitis may also be manifest. Urticaria too has been reported as a manifestation of Reiter's syndrome. The fingernails and toenails are involved in a manner that strongly resembles the changes seen in psoriasis. The nails are discolored and deep yellow keratin material accumulates under the distal portion. The entire nail may become elevated by this material. There is peri-ungual thickening, erythema, and some scaling extending over the terminal phalanges involving both the dorsal portion and the pads. Subungual abscesses may form and parts or all of the nail may be shed. Subungual hemorrhages are also reported. All cutaneous manifestations in Reiter's syndrome are reportedly seen most prominently in the patients with severe arthritis. The skin manifestations have also been reported more frequently in the venereal (endemic) types of the syndrome. Paronen makes very little mention of the cutaneous changes in the dysenteric type. Even histologically, the keratotic lesions of Reiter's syndrome resemble psoriasis of the pustular form.

The remaining changes associated with Reiter's syndrome are seen less often. The fever is quite variable or may be absent. It appears without chills and may rise 2.5 degrees or more. Neurologic symptoms point to both central and peripheral nervous involvement. There may be nerve palsies, shoulder girdle neuritis, evidence of root pain, and meningoencephalitis. There has also been reported trigeminal neuralgia and optic neuritis. Some writers maintain there is both endocarditis and myocarditis to be seen in Reiter's syndrome. Electrocardiographic changes have been observed. Some of the changes are attributed to a toxicity associated with the syndrome. Paronen lists pericarditis as an accompaniment in a few of his patients who had audible murmurs and friction rubs. He reported electrocardiographic changes in twenty instances.

Diarrhea is present in some cases. Paronen reported the largest series of 324 cases in which diarrhea occurred in 322 patients. It has been reported otherwise in only small groups. Five of the twenty-three patients reported by Hall and Finegold had diarrhea. Their cases, in contrast to Paronen's, revealed no pathogens.

Sequelae are few in Reiter's syndrome. Csonka tabulated sequelae in twenty-eight of his 185 cases. The changes consisted of recurrent iritis, foot deformities (periostitis of heels, pes valgus, pes cavus), ankylosis of peripheral joints, and sacroiliitis.

Psoriatic Arthritis

Psoriatic arthritis (arthropathic psoriasis, psoriasis with arthritis), a controversial subject ever since Alibert's original description is merging as a distinct clinical entity. There is a great deal of statistical, radiographic and chemical evidence to indicate that the concomitant presence of psoriasis and arthritis in the same individual is more than a chance occurrence, and is seen frequently enough to warrant the name of psoriatic arthritis. The incidence of arthritis in patients with psoriasis is greater than the incidence of arthritis in people who do not have psoriasis. The cause of arthritis associated with psoriasis is unknown. The theories regarding the etiology suggest a common factor for the cutaneous and joint diseases or the production of a toxin by the psoriasis in turn causing the arthritis. The second theory is of no greater help inasmuch as the primary cause of psoriasis is equally obscure. Reed and Becker note a close association between the severity of the arthritis and the cutaneous manifestation, with emphasis on the higher incidence of pustular psoriasis and psoriatic erythroderma. This is in contradistinction to Wright who found pustular psoriasis unrelated to the arthritis and who pointed out that alleviation of joint symptoms occurred in only one case when the skin was adequately treated. In this latter regard, Reed and Becker agree.

In psoriatic arthritis the association is between the skin manifestations and the joint symptoms. The cutaneous changes are frequently less extensive than the average involvement in uncomplicated psoriasis. The joint symptoms may occur in the ordinary variety of psoriasis. Some writers are of the opinion that the joint complications are seen more frequently in the pustular type of psoriasis. There are others who deny this relationship. Wright states that the palms and soles are not any more affected in patients with psoriatic arthritis than in patients with uncomplicated psoriasis. Reed and Becker state that, in general, the skin manifestations are atypical in character and distribution. The involvement on the genitals as well as the other sites of predilection, such as the elbows and knees, may present an exudative form of psoriasis. The sharply delimited plaque of psoriasis with its overlying lamellar scale is seen as the predominant feature much of the time. In this entity there is no correlated picture of conjunctivitis or urethritis. The confusion between Reiter's syndrome and psoriatic arthritis exists mainly in those cases that exhibit cutaneous or mucous membrane manifestations accompanying arthritis. In extreme cases, exfoliative psoriasis may present joint symptoms also. The outstanding psoriatic feature in psoriatic arthritis is the high incidence of nail involvement. The nail changes consist mainly of pitting, partial separation at the free border of the nail and thickening. The nails may also be eroded, irregularly laminated, and dirty white in color. The psoriatic nail is frequently brittle and the free border may be elevated by subungual keratomas. In psoriatic arthritis there is frequently involvement of the paronychial folds also with redness, edema, and scaling.

The articular lesions in psoriasis are often chronic and deforming. The most consistent joint involvement is in the hands with deformity of the distal interphalangeal joints. Epstein listed the highest incidence of joint involvement in the hands, knees, feet and ankles. Almost all the other joints may be involved. The distribution of the affected joints in rheumatoid arthritis and psoriasis is the same except that in psoriasis distal interphalangeal joint involvement is closely related to changes in the nails.

The roentgenologic changes in psoriatic arthritis are considered by many to be destructive. Most of the findings are concentrated in the digits and the spine. In x-ray of the hands, the predilection is for the terminal interphalangeal joints where erosion and fusiform change in the tips of the

terminal phalanges is seen. There is a high incidence of ankylosis, spondylitis, erosive arthritis, and sacroiliac involvement.

By way of laboratory help, Reed and Becker concluded that there was an unmistakable difference between rheumatoid and psoriatic arthritis. In addition to the help from the latex fixation test they found a marked elevation of globulins in the electrophoretic studies performed upon psoriatic patients. The elevation of β-(beta) globulin was pronounced.

The patient may appear with a painful arthritis, mucocutaneous lesions, and a readily obtained history of urethritis and conjunctivitis. The concomitant signs of arthritis and keratodermic lesions may mislead one to make a diagnosis of Reiter's syndrome rather than psoriasis as illustrated by the case presented.

Case Presentation

History.—A white, unmarried laborer, aged forty, was admitted for the first time on May 23, 1955 to the Minneapolis Veterans Hospital. He presented the complaint of a painful left hand of six days' duration. He had been previously hospitalized at a private hospital in 1949 with a diagnosis of rheumatoid arthritis involving many joints. About ten days prior to this admission he noted pain and stiffness in the left hip and pain in the right costovertebral angle area. Nine days before admission, the patient noted a creamy, uretheral discharge accompanied by dysuria. The patient received penicillin on each of three consecutive days without change in his condition. He later received sulfathiazole pills and an antibiotic capsule every six hours, with no appreciable change in the urethral discharge. Six days before admission, the patient developed a slight infection in the left thumb and the following day noted pain and swelling of the left hand and wrist. The only skin involvement at the time consisted of discoloration of all his fingernails and toenails. He had conjunctivitis which had developed one day after the urethral discharge.

Physical Examination.—Temperature 99.2. Pulse 80 and regular. Blood pressure 134/100. Patient was a well nourished, white man in no acute distress. There was a mild mucopurulent conjunctivitis as well as a purulent drainage from the right ear. A purulent urethral discharge was also present. The foreskin was reddened and appeared irritated. The prostate was enlarged and somewhat boggy. Swelling and redness of the left hand and to a lesser degree to the left wrist was recorded. There was a small paronychial infection of the left thumb. Much crusting was present on the interdigital webs of the feet. There were multiple raised lesions measuring 3 to 5 mm. in diameter and having a cornified center located on the soles and heels.

Laboratory Studies.—On admission the hemoglobin was reported as 13.1 grams. The sedimentation rate, 81 mm. per hour. The white blood count was 11,700 with 71 neutrophils, 18 lymphocytes, 7 monocytes, 2 eosinophils, and 2 basophils. On June 24, 1955 the hemoglobin was reported as 12.4 grams. The sedimentation rate, 92 mm. per hour. On admission the urinalysis was negative except for a packed field of white blood cells. Subsequent urinalysis showed varying numbers of white blood cells. Culture of the urethral discharge showed nonhemolytic streptococci. There was no evidence of gonorrhea on culture of the discharge. Mid-stream urine culture was negative for gonococci. Two blood cultures were negative. Smear and culture of the material from the right knee joint was also negative. Biopsy specimen of a skin lesion was read as keratosis blennorrhagica. The upper urinary tract was not well visualized. An intravenous pyelogram showed poor viscualization of the caliceal systems bilaterally with no particular abnormalities suggested. X-ray examination of the left hand showed minimal changes in the distal portion of the proximal phalanx of the fifth digit.

Hospital Course.—By May 31, 1955 the left costovertebral pain and tenderness had disappeared. Therapy was started with Meticorten on June 1, 1955 after a clinical diagnosis of Reiter's syndrome had been made. On June 15, 1955 the Meticorten was increased to 30 mg. per day. The lesions on the genitalia were unimproved while those on the feet showed slight improvement. Similar skin lesions were beginning to develop on the palms. On June 27, 1955 after the Meticorten was increased to 10 mg. every four hours, the patient showed some gradual improvement in his joint signs and symptoms. He was transferred to the Dermatology Service on July 1, 1955 because of the severe eruption of the feet, hands and groin. After the skin lesions became stable, the Meticorten was decreased from 45 mg. to 40 mg. daily. Inasmuch as the skin was under good control and steroid therapy and arthritis required further management, the patient was transferred back to the Medical Service on September 8, 1955. It was decided to slowly reduce his Meticorten over a one-month period. On October 17, 1955, he was started on butazolidine, 200 mg., t.i.d. The patient did well on this medication with gradual relief of joint pain. The butazolidine was gradually reduced to 100 mg., daily. On November 18, 1955 the patient began to complain of a slowing of the urinary stream and difficulty in starting the stream. There was no associated dysuria. The patient was seen in consultation by the Urology Service and was found to have a posterior bulbar stricture. He gave a history of having had

gonorrhea in 1936. While the patient was on Genito-Urinary Service, a urethrogram done on December 9 showed multiple prostatic and periurethral abscess pockets and a false passage in the bulbar urethra. There was mild trabeculation of the bladder and the lateral lobes of the prostate nearly met in the midline. An 18 Foley catheter was left indwelling until December 14. Dilatation was easy with the 28 Van Buren sound on December 19 under local anesthesia. Dilatation was recommended in another three weeks and he was sent on leave with a diagnosis of: (1) Reiter's disease and (2) Urethral stricture.

The patient was admitted about January 1, 1960 to Fargo, North Dakota VA Hospital with an eruption on the feet, right elbow and hands. According to him this was similar to the eruption he had while hospitalized in 1955. He also complained of painful aching of the feet, neck, dorsal spine, right shoulder, right elbow, and right wrist. The principal physical findings were in the skin.

Skin.—"Psoriatic" lesions were noted on the right elbow, in the palms and interdigital webs. The feet on the dorsum presented crusted papular lesions. The soles were thickened and showed considerable desquamation. The nails of both feet were likewise involved. Laboratory studies were non-contributory except for a mid-stream urine culture which was reported containing Aerobacter Aerogens and a streptococcus. During the hospital stay the patient was treated with tar ointment topically. He was given Medrol and sodium salicylate for relief of the joint pains. Marked improvement was noted early, but with reduction of the steroid the dermatitis flared up mildly. He was discharged with a diagnosis of "Rheumatoid arthritis with a psoriasis component." This forty-five-year-old white man was re-admitted to Minneapolis VA Hospital on February 18, 1960, with the chief complaint of a flare of his dermatitis and arthritis beginning August 1959. He was then well for two weeks after discharge from the Fargo, North Dakota VA Hospital, when he again had an exacerbation of his arthritis and dermatitis.

Physical Examination.—Patient was a well developed, obese white man in no acute distress. Blood pressure was 144/90; pulse was 80. Examination of the scalp revealed yellow scaling plaques extending over the hair-line in the post-auricular region. Examination of the genitalia revealed lichenification and some scaling on the scrotum as well as some scaly papules on the glans. Rectal examination revealed an enlarged prostate. Examination of the extremities revealed limitation of motion in the shoulder joints. There were erythematous, scaly plaques studded with pustules on the palms and soles, some scaly papules and plaques over the trunk, especially on the buttocks and around the anus. Thickening and discoloration of both thumb nails and all the toenails was noted.

Laboratory Findings.—Sedimentation rate was 110 mm. per hour. Urine culture showed greater than 5,000 colonies of *Aerobacter aerogenes*. Urethrogram showed diffuse demineralization throughout visualized portions of the spine and pelvis which was compatible with rheumatoid disease. There was also evidence of a rather marked stricture at the membranous portion of the urethra. Chest x-ray, urinalysis, CBC, VDRL slide test, alkaline and acid phosphatase, Uric acid, BSP, serum urea nitrogen, fasting blood sugar, serum transaminase, and electrocardiogram were within normal limits.

Hospital Course.—The patient was given 3 per cent crude coal tar for use on the body and 10 per cent ammoniated mercury in aquaphor to the scalp. On this regime his psoriasis cleared. He was referred to Urology for treatment of the urethral stricture. The Rheumatology consultant suggested giving the patient 1 gram of aspirin q.i.d. and a course of butazolidine. When the patient did not respond, Medrol was given. This regime along with physical therapy gave the patient much relief of his arthritis. A final diagnosis of psoriatic arthritis was made.

Discussion

The above case points out the difficulty encountered in a differential diagnosis between Reiter's syndrome and psoriatic arthritis. Sometimes one must wait a long time during the evolution of the disease before arriving at a conclusion. At the time of the first hospitalization the patient gave a history of purulent urethral discharge and conjunctivitis associated with paronychia, dermatitis, and arthritis. With that picture in mind, one can readily understand why a diagnosis of Reiter's syndrome was made. However, as a youth, the patient had had gonorrhea followed by a residual urethral stricture and prostatitis. The joint symptoms cleared completely. About five years later the same symptoms recurred. At the time of the last examination the cutaneous and nail finding were distinct for psoriasis. There was no evidence of conjunctivitis. There was a urinary infection with a positive culture for *Aerobacten aerogenes*. The psoriasis improved with local treatment. It is the writer's opinion that the patient had psoriasis with arthritis throughout his illness.

A summary and comparison of Reiter's syndrome and psoriatic arthritis can be graphically outlined in an abbreviated fashion emphasizing the features of arthritis, location of eruption, genito-urinary findings and course of the disease.

The Management of

ALVIN L. SCHULTZ, M.D.
Minneapolis, Minnesota

AN ASYMPTOMATIC GOITER is a frequent finding in the course of a physical examination. With the increasing life expectancy of the population the incidence of nodular goiter has also increased and the clinician is continually presented with the problem of management of nodular goiter. In each case, he must make a decision whether to advise surgical removal or merely observation. This decision is often a difficult one and is based primarily on clinical judgment. The following discussion is an attempt to outline and evaluate critically the many factors involved in management of goiter and thyroid cancer.

From the Department of Medicine of the Mount Sinai Hospital and the Jay Phillips Research Laboratory, and the University of Minnesota.
Director of Medical Education and Research, Mount Sinai Hospital, and Associate Professor of Medicine, University of Minnesota Medical School.
Presented in part at the 6th Annual Southeast Missouri Cancer Conference, Cape Giraudeau, Missouri, October 4, 1959.

Incidence of Nodular Goiter

There is considerable disagreement as to the true incidence of nodular goiter in the general population. Clinical studies and autopsy statistics are at variance. Vander and associates[1] examined 5,000 normal persons between thirty and fifty-nine years of age and found palpable nodular goiters in 4 per cent, three-fourths of which were classified as solitary nodules. Miller[2] found asymptomatic nodular goiters in 11 per cent of women. and Crile and Dempsey[3] diagnosed them in 4 per cent of patients of both sexes hospitalized for non-thyroid disorders. Perlmutter and Slater[4] reported that 4 per cent of a group of 1,000 persons without thyroid complaints had nodular goiters, and of these, 60 per cent were solitary nodules.

The incidence of nodular goiter found in routine autopsies is higher; however, many of these

Table 1
Comparison of Clinical Characteristics of Benign Nodular Goiter and Thyroid Carcinoma

BENIGN GOITER	THYROID CARCINOMA
Soft	Hard
Discrete	Irregular, invasive
Finely multinodular	Large nodules or single nodule
Stable size	Enlarging
No adenopathy	Regional adenopathy
Movable goiter	Fixed mass
Long duration	Short duration
"Hot nodule"	"Cold nodule"
Normal voice	Hoarseness
Elderly	Young

THYROID CANCER

goiters are not detectable clinicaliy. If any thyroid nodule regardless of size is included, the frequency of nodular goiter at autopsy is over 50 per cent.[5] If it is assumed that only nodules 1 cm. or more in diameter are palpable and the others are excluded, the autopsy incidence of nodular goiter is then 8 to 12 per cent.[5-7]

It may be generalized from these and other studies that the incidence of clinically detectable nodular goiter in the adult population is between 4 and 8 per cent, and that about 60 per cent of these goiters will present as solitary nodules of varying size.

Incidence of Thyroid Cancer

There is even more disagreement as to the incidence of thyroid carcinoma presenting as nodular goiter. In studies on surgical material, the incidence of cancer has been reported to be as high as 10 per cent in multinodular goiters and 33 per cent in solitary nodules of the thyroid. If patients with a preoperative diagnosis of thyroid cancer are excluded, the incidence is then given as 4 to 8 per cent of all nodular goiters removed.[4] In a series of 3,247 thyroidectomies for nodular goiter performed at the Mayo Clinic, carcinoma was found in 7.5 per cent.[8] Excluding cases in which carcinoma was suspected before operation, the incidence of cancer was 3.8 per cent. Dailey, Soley, and Lindsay[9] reported that thyroid cancer was found in only 0.2 per cent of autopsies, but was present in 4.8 per cent of their surgical cases. One thyroid cancer was reported from every 429 autopsies, compared to one cancer found in every twenty-one thyroidectomies for nodular goiter. Sokal,[10] in compiling a review of autopsy studies, reported the average incidence of thyroid carcinoma to be 0.1 per cent in 100,000 routine

autopsies. Hazard and Kaufman[11] found cancer in only 1.5 per cent of nodular goiters at autopsy, and Hull[7] reported only three unexpected cancers in a careful autopsy study of 221 thyroid glands. Alexander[12] and Hurxthal and Heineman[13] presented extensive reviews of the literature on the incidence of thyroid cancer.

It is unlikely that the true incidence of thyroid carcinoma in nodular goiter is as high as surgical studies would imply. Patients having thyroidectomies for nodular goiter are a highly selected group and usually carcinoma is suspected. Since nodular goiter is present in about 40,000 persons per million population, an 8 per cent incidence of carcinoma would indicate about 3,000 thyroid cancers per million population. Actually only about twenty-five thyroid cancers per million population are diagnosed each year.[12,14]

Diagnosis of Thyroid Cancer

The differentiation of thyroid carcinoma from benign nodular goiter is based primarily on clinical findings. The character of the mass is important. A stony hard, fixed thyroid mass, hoarseness, and palpable cervical lymph nodes all suggest malignancy. A rapidly enlarging goiter is suggestive of cancer and a localized solitary mass is more suspect than a multinodular goiter.

Benign nodular goiter is more common in women than men in a ratio of 5:1, but thyroid cancer is more frequent in men (1.7:1). The incidence of benign nodular goiter increases with age particularly after sixty. In children under fourteen years of age, about one-third of all nodular goiters prove to be carcinoma,[8] and 2 to 3 per cent of all thyroid cancer occurs in this age group.

The length of time a goiter has been present does not help much in the diagnosis of carcinoma. In the Mayo Clinic series[8] about 40 per cent of patients with thyroid cancer had a known goiter for one year or more. 30 per cent for at least five years, and 20 per cent for ten years or longer.

Toxic goiter is less likely to be cancer. The incidence of carcinoma in toxic nodular goiter has been reported to be 1 per cent, and in toxic diffuse goiter 0.5 per cent. Sokal,[10] however, disagreed with this concept. Calcification in a goiter does not always indicate it is benign, since calcium may be present in papillary carcinoma of the thyroid.

The characteristic clinical features of benign goiter and thyroid carcinoma are compared in Table I.

Thyroid function tests are generally not helpful in differentiating thyroid cancer from benign goiter. Function tests are normal except in the rare cases where carcinoma or lymphoma involves the gland diffusely and produces myxedema. In recent years the measurement of differential uptake of radioiodine over a suspicious thyroid nodule and the remainder of the normal thyroid gland has been of some assistance. The most refined techniques use an automatic scanning scintillation detector over the thyroid gland, producing a radioactivity pattern of the goiter (scanogram or scintigram). With a scanogram it is possible to establish the relative concentrations of radioiodine in different areas of the goiter. Through this technique the concept of "hot" and "cold" thyroid nodules has evolved, hot nodules concentrating more and cold nodules less radioactivity than the surrounding normal thyroid tissue. Malignant tumors almost invariably concentrate less radioiodine than the adjacent normal gland.[15-17] Means reports that he has never found carcinoma in a hot nodule. Perlmutter and Slater[4] studied eighty-five patients with solitary thyroid nodules who ultimately had thyroidectomies, and

Fig. 1. Large discrete mass left lobe of thyroid gland stable in size for five years. Remainder of gland not palpable. Scanogram reveals increased concentration of I^{131} in mass ("hot nodule").

found no cancers in twenty-four hot nodules, 20 per cent cancer in warm nodules, and 32 per cent cancer in cold nodules. They suggest that warm and cold nodules be classified together as cancer-suspect. Johnson and Beierwaltes[18] reported similar results. However, most benign thyroid adenomas also are warm or cold nodules. In general, hot nodules are very unlikely to be carcinoma and cold nodules should be treated as possible cancers. Although the scanogram is helpful, it should not be used as the sole basis for deciding whether or not to remove a suspicious goiter.

A typical "hot" nodule, is illustrated in Figure 1, and "cold" nodules in Figures 2 and 3. The value of the scanogram in determining the completeness of a total thyroidectomy, and in following the course of thyroid cancer after surgery, is shown in Figures 4 and 5. This patient had surgical excision of the right lobe and isthmus of the thyroid gland for papillary adenocarcinoma in 1943. In 1959 a metastasis to a lymph gland in the right lateral neck was removed. A scanogram at that time revealed concentration of I^{131} to the left of the thyroid cartilage in what appeared to be a normal left thyroid lobe (Fig. 4). Surgical exploration of the neck was performed and a normal left thyroid lobe was removed. No other normal thyroid tissue or carcinoma were found in the neck and the thyroidectomy was considered complete. The patient did not become hypothyroid, and a scanogram was again made eight weeks after surgery (Fig. 5). The scanogram now revealed an area of I^{131} concentration to the right of the midline. Although this new area of I^{131} concentration may have represented normal thyroid tissue left behind at surgery which subsequently hypertrophied, the patient was treated with a large dose of I^{131}. She then became hypothyroid and a scanogram revealed no concentration of I^{131} in the neck.

Removal of every nodular goiter regardless of size and character as a prophylaxis against cancer is not feasible or indicated. The number of thyroidectomies to be done would be overwhelming, and the morbidity and mortality resulting from mass goiter eradication would far outweigh the small gain in picking up a few unsuspected thyroid carcinomas. The concept that carcinoma arises from a previously benign adenoma of the thyroid is no longer accepted, and prophylactic surgery is not warranted on this basis.

Needle biopsy of a possible malignant thyroid mass should not be performed, since it is possible to disseminate the tumor locally. In addition, a needle biopsy may be misleading, for the diagnosis of carcinoma frequently requires multiple sections from different areas of the mass.

Fig. 2. Circumscribed, smooth mass, upper pole right lobe of thyroid gland. Remainder of gland not palpable. Scanogram shows concentration of I^{131} in left lobe and isthmus but poor concentration in right lobe mass ("cold nodule"). Carcinoma found at surgery.

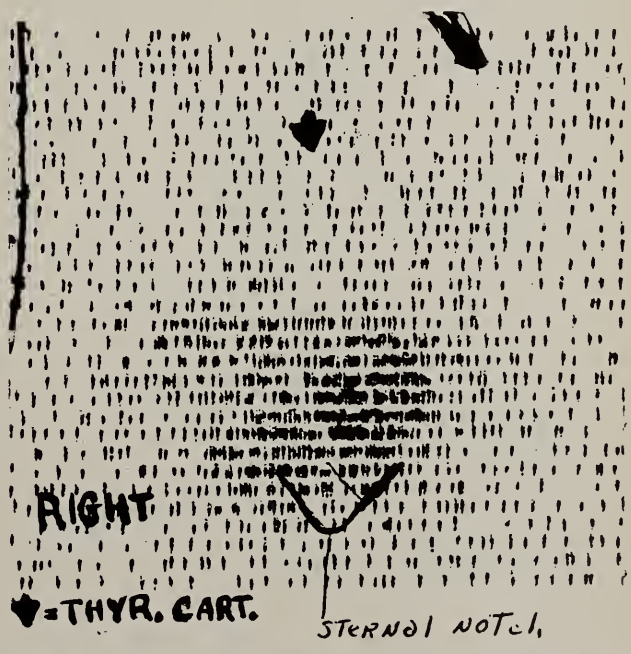

Fig. 3. Hard fixed mass right lobe of thyroid gland. Scanogram shows little concentration of I^{131} in mass ("cold nodule"). At surgery found to be Riedel's chronic thyroiditis.

Prognosis of Thyroid Cancer

The prognosis of thyroid cancer depends to a large extent on the histologic character of the lesion. Some thyroid carcinomas are relatively benign and remain localized without invasion or metastasis for years, while others may form small primary tumors spreading locally or produce distant metastases early in their course. In general, a lesion that cannot be completely resected is not curable. It has been stated that one-third of thyroid cancers are inoperable at the time the diagnosis is made.[8]

Papillary adenocarcinoma is the most frequently encountered thyroid malignancy, making up 50 to 60 per cent of most reported series.[19,20] They tend to metastasize to regional lymph nodes, but usually do not involve the capsule of the node, thus making excision possible. Invasion of the thyroid capsule and spread to adjacent tissue is common and makes total resection of the tumor difficult. Despite extensive nodal metastasis, the prognosis for long term survival and even cure is often excellent. Woolner and coworkers[21] reported fifty-three of fifty-eight patients with extensive nodal involvement alive and free of recurrence three to thirty-two years after operation. Four patients died of causes unrelated to thyroid cancer and one was not traced. In fifty-four of these cases only a modified neck dissection had been performed. These patients, however, all had so-called occult papillary carcinoma in which the primary tumor was very small but the metastasis to nodes very extensive. Papillary adenocarcinoma becomes widely disseminated through hematogenous spread only late in its course.

Malignant adenomas are usually well differentiated, encapsulated, and of low grade malignancy. Ordinarily they do not spread to lymph nodes as long as the tumor remains within its capsule. The malignant adenomas, however, are very prone to invade blood vessels and produce distant hematogenous metastases. If removed early, the chance for cure is good.

Giant cell and anaplastic carcinomas of the thyroid have a very poor prognosis. They are seldom cured and rapidly invade and metastasize. In the series of Frazell and Foote,[19] giant cell carcinoma had the worst outlook and all of their patients with this type were dead within five months after diagnosis.

There has been disagreement as to whether primary lymphoma of the thyroid ever occurs. How-

Fig. 4. Patient L. L.: Thyroid scanogram sixteen years after removal right thyroid lobe for papillary adenocarcinoma. Reveals normal functioning left thyroid lobe. No other radioactivity in neck.

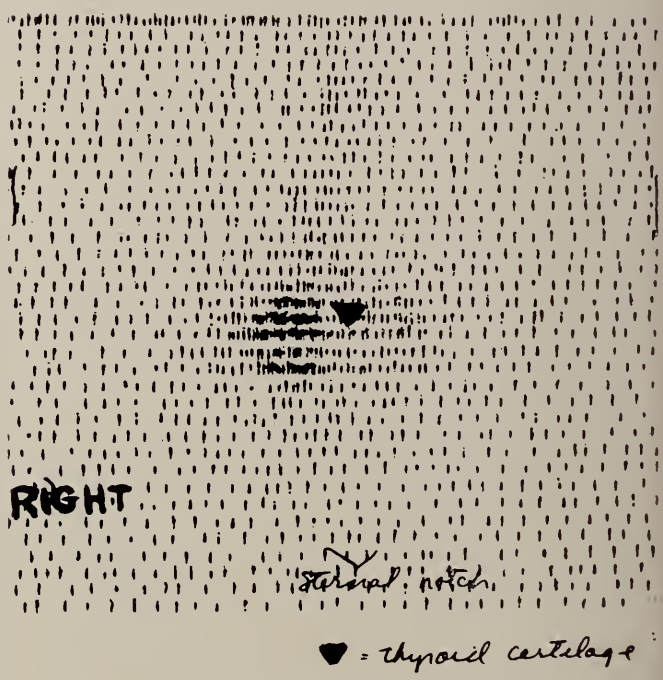

Fig. 5. Patient L. L.: Thyroid scanogram eight weeks after removal left thyroid lobe and right neck dissection. Patient euthyroid. Scanogram now reveals localized concentration I^{131} to right of midline. Treated with large dose of I^{131}.

ever, Walt, Woolner, and Black[22] recently reported eighteen cases of primary lymphoma of the thyroid, all either lymphosarcoma or reticulum cell sarcoma. These tumors were generally firm but not nodular. Eleven of their patients were dead within eighty-four months after diagnosis, but three patients with marked infiltration were still alive thirty-two, seventy-one and eighty-three months after subtotal thyroidectomy and irradiation.

Recently a medullary solid tumor of the thyroid has been described.[23] Histologically the tumor is solid and nonpapillary but frequently spreads to regional lymph nodes. It is usually well circumscribed but not encapsulated and contains deposits of amyloid. The prognosis is fair, and twelve of twenty-one patients were alive five years or more and one patient was alive twenty-seven years after diagnosis and treatment.

It is well established that many patients may live for years with persistent, incurable, thyroid cancer. Meisener and Legg[20] reported seventeen patients who lived ten years or longer with persistent thyroid cancer. The total duration of cancer in this group was ten to twenty-six years: nine patients lived ten to fourteen years and eight lived seventeen years or longer. Nine patients were still alive at the time of the report. The histologic classification was follicular in eight, papillary in six, and undifferentiated carcinoma in three patients.

Treatment of Thyroid Cancer

The treatment of thyroid carcinoma is still primarily surgical. Deep x-ray, drug therapy, and radioactive iodine are only adjuncts to adequate surgical resection of the tumor. The incidence of multicentric tumor origin within the gland is at least 20 per cent.[24] The considerations in surgery for anaplastic and giant cell tumors and lymphosarcoma are the same as for papillary cancers, although complete resection of the tumor is less frequently possible. Even in very extensive, unresectable lesions, removal of the primary tumor is worthwhile and may prolong survival.

Except for well differentiated follicular carcinoma and lymphoma, thyroid cancer is not radiosensitive. Irradiation therapy to the neck is advisable, however, in cases in which undifferentiated tumor has extended beyond the thyroid gland and cannot be completely excised. It may also be used in distant localized metastases which cannot be resected or treated with radioiodine. Although results are poor, some palliation may be obtained. Prophylactic irradiation following removal of localized thyroid lesions is not indicated.

Radioactive iodine has a limited usefulness in the treatment of thyroid carcinoma. Approximately 15 per cent of all thyroid cancers are well enough differentiated to concentrate significant quantities of radioiodine. In perhaps an additional ten per cent, tumor uptake of radioiodine can be induced or increased to the point where treatment is feasible. Excellent results with regression of tumor and prolongation of life have been reported in lesions which have a high radioiodine uptake.[25-29] However, the use of radioactive iodine is almost entirely restricted to the treatment of metastases in suitable cases, and is not treatment for the primary tumor. It is necessary to remove all functioning normal thyroid tissue before the tumor tissue will begin to concentrate enough radioiodine to make treatment possible. The remaining tumor is then stimulated maximally by endogenous pituitary thyrotropin. Administration of thyrotropin and antithyroid drugs, such as thiouracil, have been used as an additional stimulus to radioiodine uptake with variable success.[28] There is evidence that such stimulation may also result in more rapid growth of metastases.[29,30] Generally, if the tumor is not of the follicular, colloid-containing type to begin with, there is little chance that radioiodine concentration can be increased by any means. Radiation sickness, bone marrow depression, radiation pneumonitis, and pulmonary fibrosis have been produced by the large radioiodine dosage used.[31] Some patients have been kept alive and maintained in reasonably good health for ten years or longer by the repeated administration of radioiodine, and total dosage as high as 2,000 millicuries has been given over a period of years.

Replacement therapy with thyroid hormone is indicated in all patients in whom a complete resection of carcinoma is not possible, whether hypothyroidism is present or not.[29,30] It probably is advisable to place all patients on thyroid hormone after surgical resection of thyroid cancer. With the removal of much or all normal thyroid tissue in the process of resecting the thyroid

cancer, endogenous thyrotropin production is increased and results in increased growth of any tumor tissue remaining. Inhibition of this augmented thyrotropin production may be accomplished by thyroid hormone administration.

Summary

1. The true incidence of nodular goiter in the general population is between 4 and 8 per cent, and in about two-thirds the goiter is a solitary nodule.
2. The incidence of carcinoma in a nodular goiter is probably 3 to 4 per cent, and is more likely to be present in a solitary nodular goiter.
3. The diagnosis of thyroid cancer must be based primarily on clinical findings, and goiters which are clinically suspicious should be removed.
4. Surgical excision is the treatment of choice for thyroid cancer. Deep x-ray therapy and radioactive iodine should be used in the treatment of metastases which cannot be resected.
5. All patients, except those with very early localized lesions, should be placed on thyroid hormone after thyroidectomy.

Frequency of Premature Beats

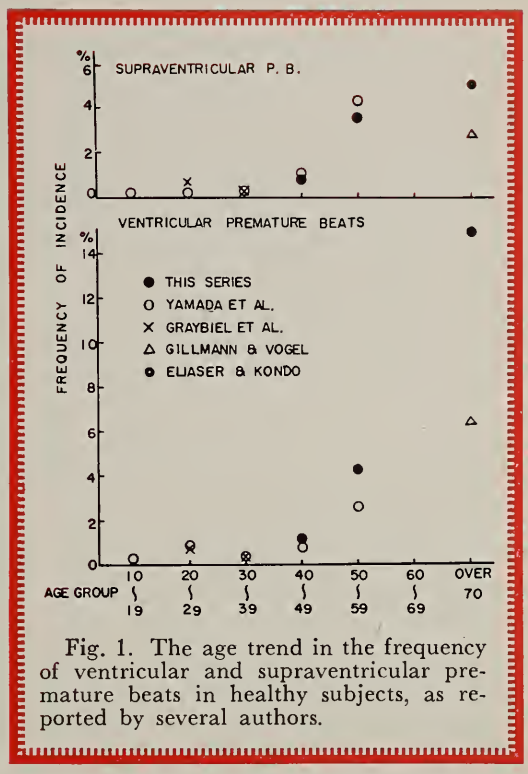

Fig. 1. The age trend in the frequency of ventricular and supraventricular premature beats in healthy subjects, as reported by several authors.

* * ** * * * * ** * * * ** * * * *

in 715 healthy adult subjects

MITSUHARU OKAJIMA, M.D.
PAUL SCHOLMERICH, M.D.
ERNST SIMONSON, M.D.
Minneapolis, Minnesota

IN CLINICAL routine electrocardiography, "frequent" premature beats are considered as "abnormal," and "occasional" premature beats are considered as "normal," but there is no clear indication of a separating critical value in the electrocardiographic literature. Thus, the judgment of a normal or abnormal frequency is highly arbitrary.

From the Laboratory of Physiological Hygiene, University of Minnesota, and Mt. Sinai Hospital, Minneapolis, Minnesota.

Supported in part by a grant from the Minnesota Heart Association.

Dr. Okajima is a Fellow, Minnesota Heart Association.
Dr. Scholmerich is Professor of Internal Medicine, University of Marbury (Germany); Fulbright Fellowship.

An "abnormal" frequency of premature ventricular beats can be determined only on the basis of the distribution in a large sample of average, healthy population. This study was undertaken in order to provide such information, supplementing previous studies.[1-5] Our sample is limited to adults over forty years, since in this age range the prevalence of cardiovascular disease is greatest.

Material and Methods

The subjects were 606 healthy middle-aged men, 294 between forty and forty-nine years of age, 312 between fifty and fifty-nine, and 109 middle-aged women, fifty-one between forty and

forty-nine years of age, and fifty-eight between fifty and fifty-nine.

The male subjects were randomly selected from a group of approximately 3,000 employees of railroad companies, collected under supervision of Dr. H. L. Taylor, Laboratory of Physiological Hygiene, University of Minnesota. These subjects were carefully screened for the presence of any objective or subjective signs of disease by a survey including personal history, blood pressure, x-ray, electrocardiography, physical examination and laboratory tests.

Most of the group of women were from employees of the Mt. Sinai Hospital, Minneapolis, but additional female subjects were obtained from the Mutual Service Insurance Company (Dr. H. Blackburn), St. Paul, Minnesota and Asbury Hospital (Dr. J. Dahl), Minneapolis.

The conventional twelve leads were taken; there were at least 40, but usually 50 to 80 beats on each of the mounted records. Single or multiple premature beats, auricular, nodal and ventricular, were listed together with the number of regular beats for each individual. Escaped beats or escaped rhythm were not included; by definition, they are not premature.

Results

Since there was no statistically significant difference in the frequency of premature beats between the male and the female groups of this series, both groups were combined in the following analysis. Table I shows a cumulative listing of the number of premature beats, absolute, in per cent of individuals of the total group, and in per cent of the total number of beats.

Thirty-three subjects (4.62 per cent of the total group) had premature beats: in sixteen, they were supraventricular; in twenty subjects, they were ventricular premature beats. Three subjects had both types of premature beats (Table I).

The total number of premature beats was eighty-one, since some of these persons had two or more premature beats. The ratio of the total number of premature beats (81) to the total number of beats (39,631) of the 715 subjects of this group was 2.04 per thousand (Table I).

A noticeable difference in the frequency of premature beats was observed between the two age groups. The incidence of persons with premature beats was about four times higher in the older (fifty to fifty-nine years) than in the younger group (forty to forty-nine years). The ratio of the number of premature beats to the total number of beats was also higher in the older group. According to the chi-square test, these differences are statistically significant. The greater frequency of premature beats in the older group was true for premature supraventricular as well as ventricular beats (Table I).

S.: Subjects with Supraventricular Premature Beats
V.: Subjects with Ventricular Premature Beats
S.&V.: Subjects with both Supraventricular and Ventricular Premature Beats

In each subject with premature beats, the number of these beats was compared to the total number of beats observed on his record. In twenty-six of the thirty-three cases (78.8 per cent) less than 5 per cent of the beats (one in twenty or more beats) were premature (Table II), but in four cases over 10 per cent of the beats were premature. In regard to the total sample of 715 subjects, the incidence of subjects with a frequency of premature beats exceeding 10 per cent is very small (0.56 per cent).

Discussion

We have compared the results of this series with previous reports concerning normal groups[1-5] (Fig. 1). The results of the various authors agree quite well on two points: (1) ventricular premature beats are more frequent than supraventricular premature beats; (2) the frequency of the premature beats increases with age.

Although the higher incidence of ventricular premature beats as compared to that of the supraventricular beats has been noted by several authors,[4-8] the difference between the frequency of these two types of premature beats in this series is small and statistically not significant.

The increase in the frequency of premature beats between the two age groups, forty to forty-nine and fifty to fifty-nine, in this series, coincides remarkably well with the increase in these age groups of 4,236 Japanese industrial employes.[1] In all reports of normal groups available so far,[1-5] where at least 100 subjects were investigated, the frequency in age groups below thirty-nine years of age is smaller than in the forty to forty-nine age group of this series. The frequency of premature beats in healthy subjects older than sixty years is still higher than in the fifty to fifty-nine-year age group of this series (Fig. 1).

The results show that age is an important factor in the frequency of premature beats. It is of interest that the age trends of premature beats parallel the prevalence of coronary heart disease. It may be suggested, therefore, that an underlying cause for the age trends of premature beats may be small ischemic areas, giving rise to the formation of excitable foci.

Although the occurrence of premature beats observed in our material is not abnormal, it may well have some prognostic significance as an early sign of localized myocardial involvement. Therefore, a follow-up of subjects with frequent premature beats may be desirable. The arbitrary selection of a ratio of 10 per cent premature beats in an individual record used for the classification code proposed by Blackburn, Keys, Simonson, Rautaharju and Punsar[9] is supported by the present data. If anything this criterion is conservative.

Summary

1. The frequency of premature beats in a normal group of 606 men and 109 women, ranging between forty and fifty-nine years of age, was investigated.

2. The frequency of premature beats is much higher in the older group (fifty to fifty-nine years of age) than in the younger group (forty to forty-nine years of age) in regard to the number of beats as well as number of subjects. The difference was statistically significant.

3. The incidence of premature ventricular beats is slightly higher than that of premature supraventricular ones.

4. In 78.8 per cent of the subjects with premature beats they occurred less than once in twenty heart beats; but in four of the thirty-three persons they occurred once or more in ten heart beats.

5. In view of the age trend, it is suggested that premature beats may be due to small ischemic areas in the myocardium.

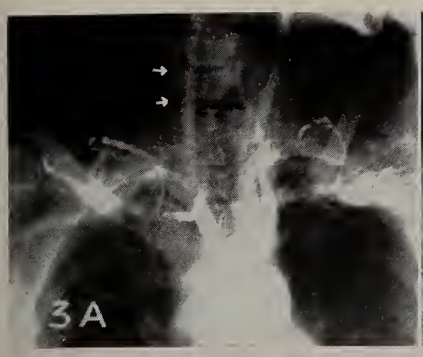
Intravenous



S. B. FEINBERG, M.D.
M. E. GOLDBERG, M.D.
Minneapolis, Minnesota

EVER SINCE Moniz[8] introduced successful cerebral angiography in 1927, innumerable articles have appeared concerning the introduction of radio-opaque contrast media into venous and arterial routes. Forward intravenous cardioangiography, translumbar aortography, selective cardioangiography, and selective angiography are only some of the methods used, but these will not be reviewed here. The purpose of this paper is to re-emphasize the feasibility of intravenous angiography rather than reiterate the problems of other methods.[1,6,7] As a preoperative diagnostic procedure, this method is simple and requires a minimal number of instruments as compared with the others mentioned above.

As long ago as 1948, Weens,[13] as well as other authors[3,9,10,11] suggested intravenous aortography, particularly for nephrography. The reason for its advocacy was to avoid the complications of translumbar and direct renal artery selective angiography.[6,14] Steinberg has also advocated selective intravenous aortography for visualization of the thoracic aorta.[10]

One might assume that the relative lack of interest in this simple procedure was related to

From the Mt. Sinai Hospital and University of Minnesota Department of Radiology.

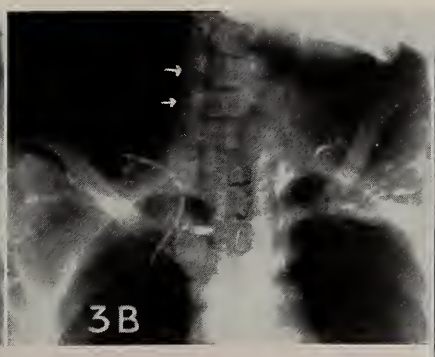


Fig. 3 (a and b). Clinical question of common carotid syndrome disproved by delineation of normal carotids and vertebral arteries as well as delayed jugular return.

Fig. 4. Stasis of contrast media in left atrium owing to mitral stenosis is shown, even on delay film, sixteen seconds after injection. Patient was studied because of an atypical mitral murmur, suggesting a left atrial tumor.

Angiography

its place in a small, well equipped, general hospital

the fact that the vascular bed was visualized only faintly by this method. This can be readily understood, for only 30 to 50 cc. of 70 per cent Diodrast was used. It was introduced through direct venopuncture, using a hand syringe. As a result, adult intravenous angiography was far from being vividly graphic. New contrast media renewed interest in the method.[4]

Bernstein and Greenspan[2,5] were impressed by the need for a relatively simple approach to the preoperative diagnosis and localization of aortic aneurysms and occlusions of the arteries which might be amenable to removal and replacement with prostheses. Because selective aortography and angiography, particularly in the group with occlusions of the iliac arteries, is not without hazards to the older and often debilitated geriatric patient, these authors advocated the revival of the intravenous method using a combination of higher concentrations of iodinated compounds in larger doses, rapid injection, and rapid film changers.

After the feasibility and safety of this method were proved, we were invited by R. H. Greenspan to join the project in order to study its application in both large and small hospitals.

The purpose of the project was not merely to

increase the scope of the original series at the University of Minnesota Hospitals but also to advocate it as a practical tool for use in smaller units where good laboratory, anesthesia, surgical, and surgical care units are available. Our experience has proved to our own satisfaction that this procedure has been a boon to vascular surgery at Mt. Sinai Hospital, Minneapolis. This has facilitated the handling of the older patient thereby limiting the use of selective angiography, operative or percutaneous, for special problems.

Technique

One of the most important phases of the procedure is the selection of the proper contrast media. In order to deliver a sufficiently concentrated bolus of contrast to the left heart and aorta, a large volume of concentrated iodinated contrast, either 90 per cent Hypaque or 85 per cent Renografin is used. The volume used is approximately 1 cc. per kg. up to a total of 100 cc. The average dose for an adult varies between 70 and 90 cc.

As one might suspect, the speed of injection is almost as important as the contrast media. A polyethylene venous catheter of maximal diameter (4 mm. outside diameter) is inserted into the antecubital vein as far as possible, usually 4 to 8 inches. It is a necessary adjunct, for trochar or needle injections were not as satisfactory. Using an Elema-Schonander mechanical injector, the bolus is injected in its entirety within 1 or 2 seconds.

We use the Decholin circulation time as a guide to the delay between injection of contrast and the beginning of the exposure sequence. The following times have proved to be satisfactory in an average sized adult.

Location	*Delay Between Injection and Exposure*
Right heart and pulmonary artery	no delay
Pulmonary vein, left atrium and left ventricle	2-3 sec.
Asc. aorta and aortic arch	5-6 sec.
Thoracic aorta and upper abdominal aorta	9-10 sec.
Aortic bifurcation	10-11 sec.

A Schonander rapid film changer is used at a rate of one to one-and-a-half exposures per second.

At this point one must acknowledge a recently published modification of intravenous aortography[12] in which the contrast media was injected simultaneously into both antecubital veins using a hand syringe technique. We prefer our technique for the reasons of more certain timing, speed of injection, and serial filming of the various phases of filling the vascular system. The hand technique relies on the manual changing of a limited number of cassettes. Thus, it is considered acceptable in a limited sense, if one is aware of the unpredictability of the speed of the hand injection and of the exact timing of the exposures.

The patient is sedated before coming to the x-ray department. A scout film is taken. While this is being processed, the circulation time is determined and the venous cut-down is performed. During these procedures, the patient is told about the intense, momentary flush reaction he will likely experience. With the preliminaries finished, the examination is completed with dispatch.

Uses of Intravenous Angiography

Now that the technique has become routine in our department, we use it for many purposes. It has proved to be extremely helpful in evaluating the great vessels of the neck, for example, common carotid arteries (Fig. 1). In this regard it is excellent for excluding innominate aneurysms or mediastinal tumors (Fig. 2) or both. We have held the opinion that it is not a substitute for cerebral angiography but have found it suitable for the delineation of the origin of the vertebral arteries and for demarcation of the jugular vein (Fig. 3a and 3b). We prefer selective cardioangiography, if technically feasible, in congenital heart disease or intracardiac chamber study. Nevertheless, one can demonstrate chamber defects or some valvular defects by this method, for example, high grade delay of outflow of contrast media from the left atrium in mitral stenosis (Fig. 4). We have found it helpful in delineating coarctations and the associated changes in the arteries in the region of the aortic arch as a consequence of coarctation (Fig. 5). It has proved extremely valuable in dilineating the cause and extent of occlusions of the arteries. It is of value in studying the aneurysmal changes in the thoracic aorta. A good example is that of a traumatic aneurysm immediately distal to the arch (Fig. 6). The abdominal aorta and its tributaries are usually well outlined (Fig. 10a). A malignant renal neoplasm is identified from the initial fill of its vessels, through the capillary phase, and the final "tumor stain" phase (Fig. 7).

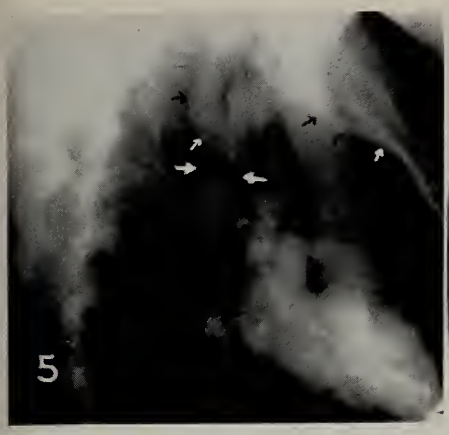

Fig. 5. Intravenous angiogram of a twenty-year-old girl with hypertension and absent pulses of the femoral arteries shows coarctation of the junction of the distal aortic arch and descending thoracic aorta. The aorta distal to this coarctation is not dilated intimating an extremely small aperture. The subclavian and internal mammary arteries are dilated. The dilated subclavian and internal mammary vessels and coarction site are indicated by arrows.

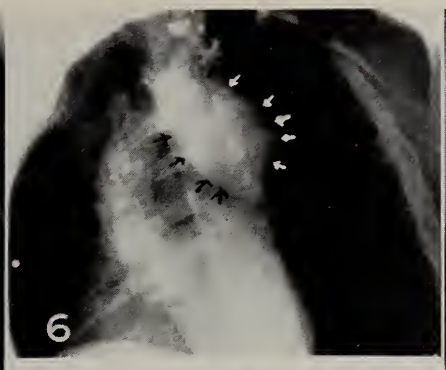

Fig. 6. A large post-traumatic spherical saccular aneurysm at the junction of the aortic arch and descending aorta.

Fig. 7. Increased blood supply to neoplasm of upper pole of kidney which on I.V.P. could not be differentiated from a cyst.

Fig. 8. Palpable abdominal aortic aneurysm. The aorta is "normal" below the renal arteries thereby prompting successful surgery. The arrows show renal arteries and aneurysm.

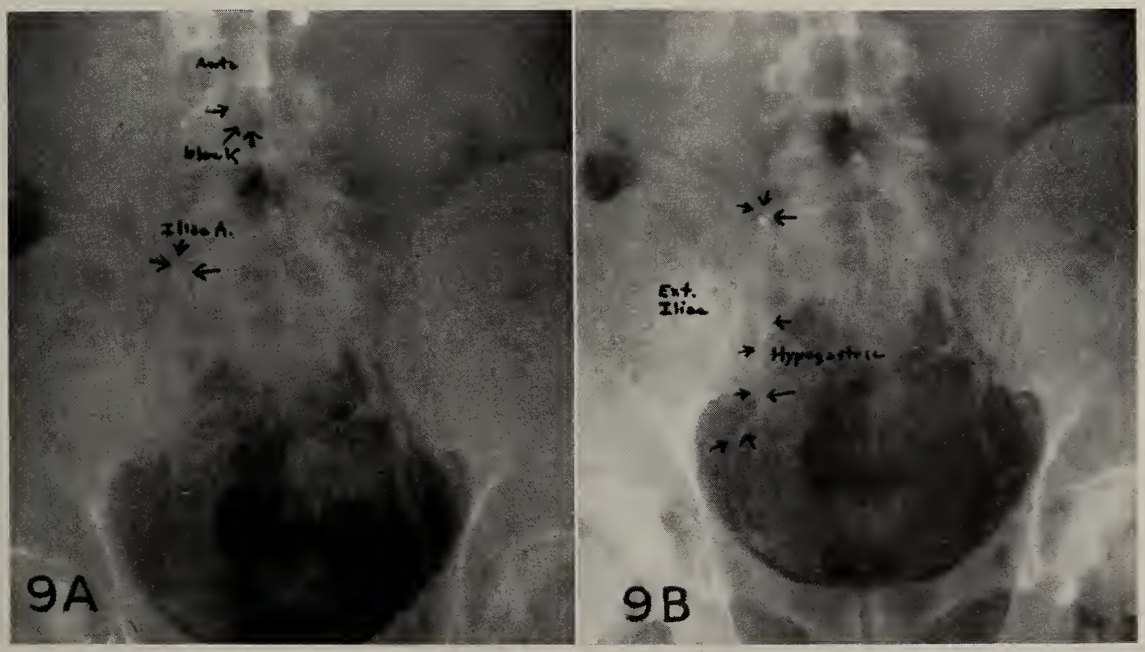

Fig. 9 (a and b). Decreased pulsations of the right femoral artery. Occlusion found in the right side of distal aorta. The external iliac artery is filled by collaterals. Hypogastric artery only partially filled.

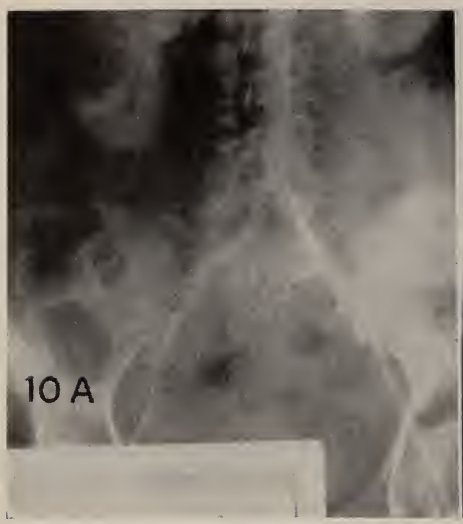

Fig. 10 (A) Decreased pulsations of right femoral artery. Survey femoral run-off cassette seen superimposed on femoral triangle. Aorta and iliacs are normal. Survey femoral run-off film showed poor caliber of femoral artery. (B) Direct femoral arteriogram confirmed above findings showing diminution of overall caliber of femoral artery and multiple plaques.

Fig. 11. Femoral artery run-off study performed because of lower extremity circulatory problem shows normal femoral arteries, and increased vascularization in pelvic bones in zones of known Paget's disease.

Abdominal aneurysms are obviously easily identified (Fig. 8). Distal aortic blocks are identified also as to site and extent prior to surgery (Fig. 9a and 9b). It can be used also to check on the femoral artery run-offs to determine the pressure of a distal femoral arterial block which can be confirmed by means of conventional direct femoral arteriogram (Fig. 10a and 10b). In one case in which it was desired to evaluate the femoral arterial run-off, an interesting aside was that of increased blood flow to the bone owing to Paget's disease (Fig. 11). It has been of value also in demonstrating decreased blood flow to an isolated kidney in a case of "idiopathic" hypertension.

Conclusion

Using the rapid injection of large quantities of highly concentrated iodinated contrast media coupled with a rapid film changer, one can employ intravenous angiography as a simple and safe means of diagnosing and evaluating multiple vascular and non-vascular lesions in the course of the great vessels and their immediate branches. The need and feasibility of surgical treatment can be determined.

Endosalpingiosis

A case report and discussion of etiology presented at the Minnesota State Society Obstetrical and Gynecological Meeting, St. Paul, Minnesota, November 7, 1959.

MELVIN B. SINYKIN, M.D.
Minneapolis, Minnesota

ENDOSALPINGIOSIS is a disease that resembles endometriosis except that the aberrant glandular epithelium shows histological characteristics of tubal epithelium and lacks the cellular stroma associated with endometrium. Sampson[1] first used this term to describe extension of tubal epithelium from tubal stumps following salpingectomy. He showed that the new tubules perforated not only the muscularis of the tube but also the serosa. Involvement of the bowel was found in six patients and involvement of the ovary in four patients. In later studies Sampson[2] showed that aberrant tubal epithelium can be found in laparotomy scars after surgery involving the fallopian tubes.

Dr. Sinykin is Attending Obstetrician and Gynecologist, Mount Sinai Hospital, Minneapolis, Minnesota.

Goodall[3] published his experience with endometriosis and endosalpingiosis in a monograph published in 1943. He states that endosalpingiosis was always associated with a mild catarrhal type of subacute salpingitis. The inflammation was said to produce a marked tendency to hypertrophy of the tubal epithelium without closure of the fimbrial ends and without inflammatory infiltration of the muscular wall of the tube. Goodall found that endosalpingiosis rarely occurred in the form of implants as seen in endometriosis. He attributed this to the resistance of pelvic peritoneum to the spread of endosalpingiosis. When implants were found they were usually localized to the peritoneum in the immediate vicinity of the involved tube or ovary. Goodall,[3] Powers,[4] and Bianco[5] have described cases in which the surface of the ovary contains heterotopic endosalpingeal tissue. The descriptions of the gross appearance of the ovarian involvement varies from that of small implants surrounded by loose edematous stroma to that of solitary fibrous nodules in which glandular acini are found with the histological characteristics of tubal epithelium. The incidence of endosalpingiosis of the ovary is small. Bianco[5] found endometriosis in seventy-nine ovaries and endosalpingiosis in two of a total of 562 ovaries routinely examined following surgery.

Report of a Case

The following is a report of what is believed to be an unusual case of endosalpingiosis with involvement of the right ovary, right fallopian tube and pelvic peritoneum:

M.L. (30489), a woman, aged forty-six, para O, admitted October 14, 1958 to Mt. Sinai Hospital for pelvic laparotomy. A right adnexal cystic mass had been detected during hospitalization for pneumonia in June, 1958. The tumor had been asymptomatic until two weeks before admission when pelvic pressure was noted. Pelvic examination showed a right adnexal cystic mass, moveable, and 10 cm. in diameter. Pelvic laparotomy was performed October 15, 1958. A right ovarian cyst that appeared to be a simple cyst was found. A single nodular excrescence was seen near the mesentary of the ovary. Patches of small yellow-grey nodules were seen along the uterovesical peritoneal reflection and along the posterior surface of the uterus extending along the right cornual region and the posterior leaf of the right broad ligament. The nodules were discrete, about 1 to 2 mm. in diameter and did not extend deeper than the serosa.

A few nodules were removed for frozen section, but an exact diagnosis could not be given. Because well differentiated carcinoma was not ruled out, total hysterectomy and bilateral salpingo-oophorectomy were performed. The pathology report submitted by Steven Barron, M.D., pathologist at Mt. Sinai Hospital is abstracted as follows: The right ovarian cystic mass measures 11 cm. in length and 7 cm. in diameter. On cut section the lumen is multilocular. The lumenal surface is smooth with some areas of granularity. Sections of the ovarian cyst show a benign multilocular serous cystadenoma with nodules of endosalpingiosis. On the serosal surface of the uterus are numerous nodules which are fibrous and in many of these nodules small cysts are seen lined by columnar epithelium. In places small papillary projections extend into the lumen of the cysts. Some cells are ciliated. The cellular structure resembles that seen in the fallopian tube. Cysts of this type are found also on the fallopian tube and on the right ovary. No blood is seen within the cysts and no endometrial stroma surrounds the cysts. This appearance is typical for endosalpingiosis.

When the above report was received, the pathology department was asked to make multiple sections through the interstitial and isthmic portions of the right tube since the peritoneum in this area contained many clusters of nodules. Review of these sections showed many epithelial offshoots from the isthmic and proximal ampullary portions of the tube. (Figs. 1 and 2) These offshoots are seen to penetrate the muscular wall of the tube and to reach the serosal surface where the microscopic appearance of the small cysts are the same as seen elsewhere on the adjacent pelvic peritoneum (Fig. 3) and ovary. (Fig. 4)

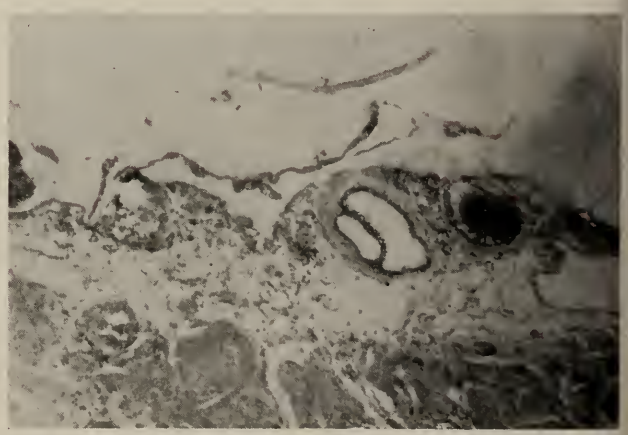

Fig. 3. Nodule of endosalpingiosis in serosa of uterus.

Fig. 4. Endosalpingeal cyst in hilum of the right ovary.

Discussion

Endosalpingiosis is a disease process resembling endometriosis except that it is less frequent and has much less tendency to spread to the surrounding tissues. The case presented raises some interesting questions: (1) Do the offshoots of tubal epithelium represent what is usually described as salpingitis isthmica nodosa? If so, the nodules on the isthmic portion of the tube are much smaller than usually described, but may fit the description of Novak and Novak[6] who state that the size of the nodules may be as small as buckshot. (2) Do the similar nodules disseminated to the surrounding pelvic peritoneum represent implantation of tubal epithelium that has perforated the wall of the tube? This is possible according to Sampson's theory and would also explain the involvement of the ovary. (3) Does the presence of serous cystadenoma of the right ovary as well as nodules of the endosalpingiosis support the theory of metaplasia of the germinal epithelium of the ovary and pelvic serosa? Robert Meyer, Emil Novak, and more recently Gardner, Greene, and Ranney[7] have supported this theory. However, since the demonstration of the implantation theory in monkeys by TeLinde and Scott[8] and of the viability of menstrual endometrium in humans by Ridley and Edwards,[9] Gardner *et al*[10] have published a letter to the editor of the *American Journal of Obstetrics and Gynecology* re-evaluating the histogenesis of endometriosis and admitting that retrograde menstruation may be one of the causes of endometriosis.

The treatment of endosalpingiosis is similar to that of endometriosis. Since the gross appearance of the lesion is quite variable, the diagnosis is usually made only after histological study. In the case reported above, a laparotomy was performed because of a right ovarian cyst. Since exact diagnosis could not be given on frozen section and because of the patient's age, total hysterectomy and bilateral salpingo-oophorectomy were performed. The descriptions of Sampson[1] led to the practice of performing cornual resection in order to avoid tubal stumps and subsequent endosalpingiosis or endometriosis. The type of endosalpingiosis found in this patient presents a different appearance than endometriosis because it does not invade or produce bloody cysts as in endometriosis externa. The findings in this case of endosalpingiosis would appear to support the implantation theory since the distribution of the nodules is centralized at the site of penetration of the tubular offshoots from the isthmic portion of the tube.

Summary

A brief review of endosalpingiosis is presented together with an unusual case of endosalpingiosis presenting involvement of the pelvic peritoneum, the serosa of the uterus, the right tube, and right ovary. The case raises certain theoretical questions related to the etiology of endometriosis and endosalpingiosis.

Report of Case

Myocardial Infarction

with Normal Master's Test

EDUARDO DELOS SANTOS, M.D.
Minneapolis, Minnesota

IT IS NOT infrequent that patients with symptoms of coronary insufficiency (angina pectoris) show normal electrocardiographic patterns. The rule, however, is that sometime in the course of the disease, electrocardiographic changes usually appear. If repeated or serial electrocardiograms persist in being normal, an exercise test often reveals coronary insufficiency (ischemic response).[1-3]

The following case report is an example of the infrequent case of coronary disease with normal resting electrocardiogram and negative exercise test (Master's two-step) twelve days before death, with confirmatory autopsy findings.

Report of a Case

B. G., a white man, aged sixty-four, was admitted to Mount Sinai Hospital Medical Service March 23, 1960. He complained of severe chest pain of one hour's duration following grocery shopping with his wife. He died twenty minutes after admission to the hospital.

Dr. delos Santos is a Medical Fellow, University of Minnesota Graduate School and Mount Sinai Hospital.

Electrocardiograms showed an acute postero-lateral wall infarct (Fig. 1) with terminal ventricular fibrillation. His past history revealed typical attacks of angina pectoris "with left anterior chest pain radiating to the left arm associated with exertion" during the past year; usually immediately relieved by nitroglycerin and by rest.

The patient was first seen at Mount Sinai Hospital Outpatient Department on November 4, 1959, with complaints of severe left chest pain radiating to the left arm and back with associated shortness of breath and sweating. Physical examination was essentially negative. An electrocardiogram showed normal pattern (Fig. 1). The patient was sent home with instructions to continue using nitroglycerin for chest pain.

The patient was again seen in the Outpatient Department on January 11, 1960, with complaints of impairment of vision, anterior chest pain, shortness of breath and intermittent claudication of the left leg. For the past twenty years there had been progressive impairment of vision and he had to change glasses every two to four years. The precordial chest pain had been recurrent for the past year. For about the same duration, the patient had pains in both legs, more on the left, noted especially when walking. The rest of the past history revealed that he had a right nephro-lithotomy in 1937, followed by nephrectomy for nephrolithiasis in 1940; syphilis treated in 1935 and 1940 with heavy metals, in 1954 with 30 million units of penicillin; recurrent duodenal ulcer treated in 1942, 1945, 1956, and 1958. In 1956 he was known as a treated case of tertiary syphilis. All of the above hospitalizations were at another facility in Minneapolis. A routine electrocardiogram on his 1956 hospitalization was reported as normal, as were two others taken in November and December, 1958.

The physical examination findings on January 11, 1960, revealed a well developed and well nourished male in no distress. The blood pressure was 170/80, pulse 82 per minute and regular. Examination of the eyes showed decreased vision in the left eye, an enlarged right pupil which did not react to light but had good reaction to accommodation. There was an early cataract in the left eye; nerve head changes suggestive of optic atrophy in

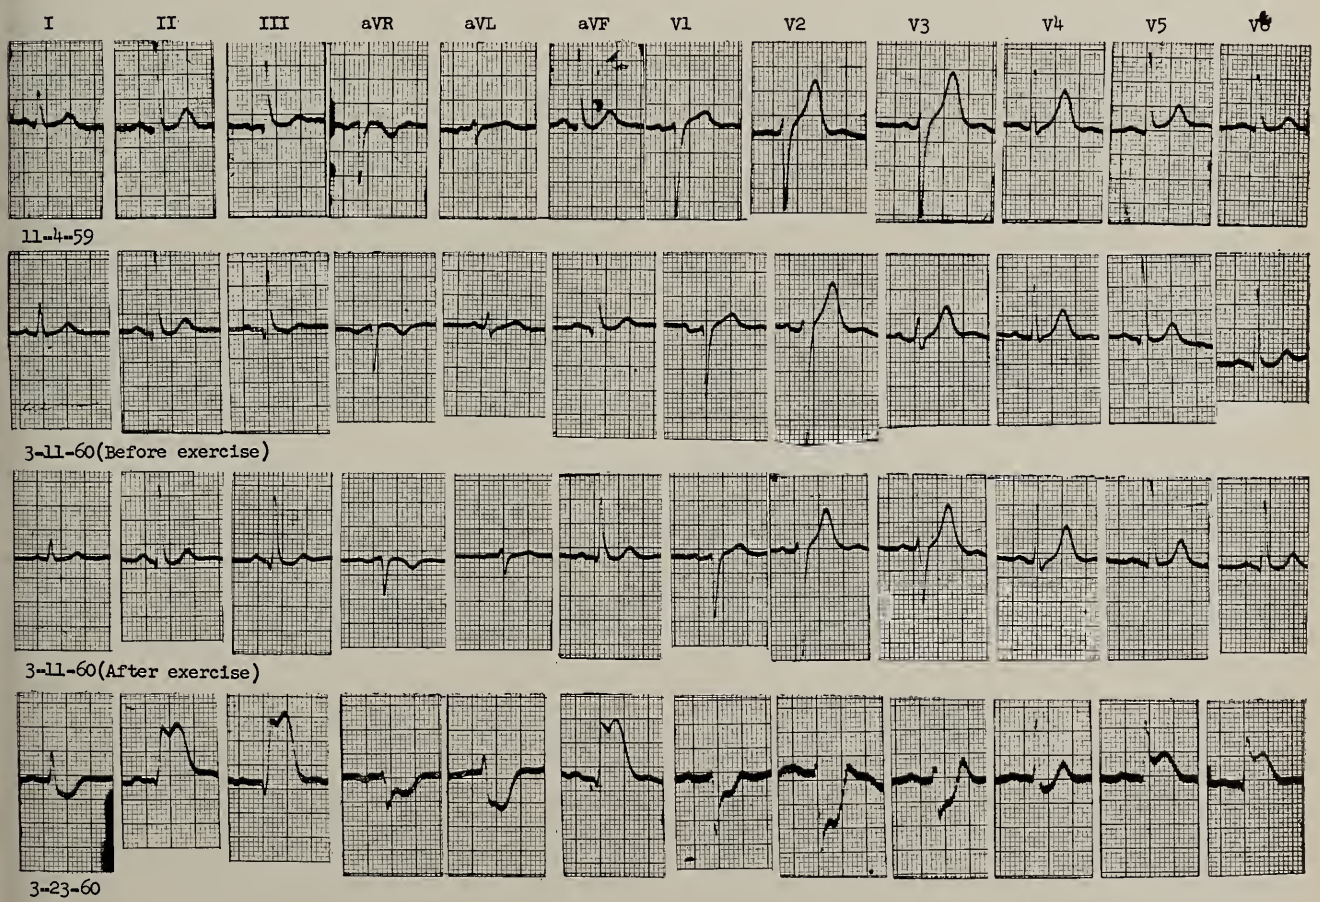

Fig. 1. Serial electrocardiogram of patient with angina pectoris: November 4, 1959, initial electrocardiogram. March 11, 1960, resting electrocardiogram before Master's two-step test. March 11, 1960, electrocardiogram after Master's two-step test. (All above electrocardiograms were interpreted as normal). March 23, 1960, electrocardiogram shows evidence of injury with pronounced S.T. elevations in L2-3-A.V.L., V5 and V6 with pronounced reciprocal S-T depression in L1-A.V.L., V1 to V3. Shortly after the ECG, ventricular fibrillation developed.

both eyes and constriction of the visual fields on both eyes. Examination of the fundi showed grade I retinal vessel changes. There was impaired hearing on the right side. Examination of the neck was negative. Chest was clear. The heart was not enlarged to percussion, the heart tones were slightly muffled. There was no murmur or rub heard. The abdomen was essentially negative. Rectal examination showed slight enlargement of the prostate. The extremities showed no edema. The femoral pulse on the left was weak and the distal pulses to the left leg were not appreciated. Oscillometry readings of the legs taken at the mid-thigh and mid-leg regions showed 1 to 2 units on the left leg and 3 units on the right leg. Deep tendon reflexes showed no gross abnormalities. Toe signs were absent.

The patient was followed as an outpatient, only, and had four subsequent visits. He continued to complain of pains in the chest and legs which at the time were considered unlikely to be the girdle and lightning pains of lues. The pains were considered characteristic of arteriosclerotic heart disease. On January 15, 1960, the hemaglobin was 15.8 gm. per cent, leukocytes 13,500 per cubic mm. with 70 per cent neutrophils, 25 per cent lymphocytes, 4 per cent eosinophils, 1 per cent basophils. An electrocardiogram was normal. Chest x-ray showed the heart to be of left ventricular configuration with aortic arch calcification. The lung fields were clear. The serum cholesterol was elevated to 280 mg. per cent. On February 22, 1960, a spinal tap revealed normal spinal fluid including pressure, cytology, serology, and chemistry. The patient was continued on nitroglycerin and given Niamid 25 mg. t.i.d. and Darvon compound. On his third visit on February 22, 1960, he complained of sharp chest pains on the right side. He described them as "needle pricks" noted on deep inspiration. However, the physical examination findings were unchanged. His subsequent visit was on March 7, 1960, and at this time he was free of pain. He appeared less depressed, probably the effect of Niamid. The blood pressure was 190/95 mm. Hg. The pulse was 72 per minute, regular. Chest was clear. The heart findings were unchanged. On March 9, 1960, an upper gastrointestinal series showed a duodenal bulb deformity suggestive of an active ulcer crater or the site of an old healed ulcer with residual excavation. Circulation time done on March 11, 1960, was 14 seconds. Vital capacity was 3 liters total and 2.4 liters in two seconds. He was put on convalescent ulcer diet and antacids.

On March 11, 1960, a Master's two-step test was performed and both resting and exercise electrocardiograms were normal (Fig. 1). The last visit to the Outpatient Department was on March 14, 1960, when the patient continued to complain of pains in the anterior chest and dyspnea. The blood pressure was recorded as 190/90, the pulse 82 per minute. The chest was clear and the heart was regular, with occasional premature ventricular beats. There was some epigastric tenderness noted. The femoral pulses were weak bilaterally. The rest of the examination was unchanged. The patient was continued on the same ulcer regime. He was given a return appointment ten days later which was March 24. However, he was admitted to the hospital on March 23, where he expired of myocardial infarction, as previously described.

Clinical Diagnosis: (1) Arteriosclerotic heart disease, angina pectoris, acute postero-lateral infarct (and ventricular fibrillation by electrocardiogram). (2) Arteriosclerosis obliterans of lower extremities. (3) Tertiary syphilis with argyll-Robertson pupil, bilateral optic atrophy. (4) Duodenal ulcer, probably inactive.

At autopsy, moderate cardiomegaly was present. There was marked narrowing and complete occlusion of the right coronary artery with thrombus and atheromatous material. There were scattered acute ischemic myocardial changes in the posterior interventricular septum. The left anterior descending coronary artery showed moderate narrowing and areas of hypoplasia with pinpoint lumen. There was minimal myocardial scarring. Microscopic sections of the myocardium and coronary arteries confirmed the above gross findings. There was marked aortic atherosclerosis. A healed prepyloric gastric ulcer was found.

Comment

In reviewing the case, in retrospect it is of interest that in spite of typical subjective symptoms of coronary insufficiency (angina pectoris), repeated electrocardiograms were normal, including an exercise test twelve days before the terminal myocardial infarction. Therefore, coronary arteriosclerosis confirmed by autopsy, sometimes cannot be demonstrated by the electrocardiogram.

Summary

A case of coronary artery disease with normal serial and resting electrocardiograms and negative Master's two-step test twelve days before death due to acute myocardial infarction is presented with confirmatory autopsy evidence.

Acknowledgment

Acknowledgment is made to Dr. Ernst Simonson, Professor, University of Minnesota, and consulting electrocardiologist at Mount Sinai Hospital, for his helpful suggestions and criticisms.

Report of Case

Duodenostomy

for difficult duodenal closure

GEORGE WERNER, M.D., F.A.C.S.
Minneapolis, Minnesota

MUCH OF THE effort to develop new operations for management of duodenal ulcer resulted from a desire to avoid the technical difficulties associated with surgery of the duodenal stump. Subtotal gastrectomy, however, continues to remain the operation of choice of most surgeons for the operative treatment of duodenal ulcer. Secure closure of the duodenum in this operation is extremely difficult sometimes, and on, occasion, impossible. In the past, surgeons have used various techniques to make closure more satisfactory or to circumvent the problem, however no technique has proven universally satisfactory.

One of these techniques is duodenostomy or duodenal decompression. Several recent enthusiastic reports suggest that more surgeons are accepting duodenostomy occasionally as an accompanying procedure to gastrectomy, and are having low morbidity and mortality rates in connection with it. Two cases in which duodenostomy was used successfully are presented.

Dr. Werner is on the Attending Surgical Staff, Mount Sinai Hospital, Minneapolis, Minnesota.

Report of Cases

Case 1.—M. M., a man, aged forty-eight was admitted on January 10, 1958. He had had a known duodenal ulcer for the past one-and-a-half years which had been treated by diet. On the day prior to admission he began having tarry stools and on the day of admission, he had hematemesis.

Examination on admission revealed a blood pressure of 130/90, a pulse of 110, and the hemoglobin was 12.1 grams. There was mild epigastric tenderness.

A nasogastric tube was inserted and a continuous milk drip was started. The patient's condition remained unchanged until the following day. Active bleeding started again and his hemoglobin dropped to 9.1 grams while receiving five units of blood, and the decision to operate was made.

At surgery, examination of the duodenum revealed a previous anterior perforation which had been covered by omentum. The bleeding was coming from an open vessel in the base of a large posterior ulcer which penetrated into the head of the pancreas. The duodenum was considerably shortened and the common duct was seen entering the duodenum just distal to the ulcer.

The bleeding vessel was ligated and it was then apparent that the closure of the duodenum would be hazardous and insecure. A Billroth II, Hoffmeister, retrocolic, subtotal gastrectomy was done. The nasogastric tube was threaded into the afferent duodenal

loop, and a 16 F. straight rubber catheter (with two additional holes) was sutured into the duodenal stump. The duodenal stump was closed about the tube as well as possible. Absorbable sutures were used. The catheter was brought out to the skin through a separate stab wound. The tract from the duodenum to the skin was made long and was covered by omentum. In addition a penrose drain was placed near the duodenal stump and brought out to the skin. Postoperatively the nasogastric tube and the duodenostomy tube were connected to suction. The drainage from the two tubes on successive postoperative days were as follows:

	1	2	3	4	5	6	7	8	9	10	11	12
Nasogastric Tube	500	375	950	200								
Duodenostomy Tube	150	50	50	50	50	50	250	250	250	900	650	750

The nasogastric tube was removed on the fifth postoperative day and the patient started on oral feedings. The duodenostomy tube was clamped on the twelfth postoperative day and removed on the twenty-first day. The patient was discharged from the hospital on the sixteenth postoperative day. The penrose drain was gradually removed while the patient was in the hospital, and there was very little drainage. After removal of the duodenostomy tube the fistula drained slightly for twenty-four hours and then stopped.

Case 2.—C. C., a man, aged forty-nine, had had a known duodenal ulcer for the previous fifteen months. He had followed medical ulcer management carefully but would develop symptoms on the slightest relaxation of diet. During the month prior to admission he had frequent nausea and he vomited almost daily. There had been a moderate weight loss, and x-ray examination revealed gastritis, duodenitis and a small ulcer crater in the cap. The stomach was dilated, suggesting obstruction, but there was immediate emptying at the time of the examination.

Because the patient had failed to heal the ulcer on a satisfactory medical regimen, surgery was recommended. At operation it was found that the antrum, duodenum and head of the pancreas were involved in one inflammatory mass. A difficult duodenal closure was anticipated and alternate methods were considered. An attempt was made to free the antrum from the pancreas. A tissue plane was found and the antrum gently and slowly was freed from the pancreas by blunt dissection. When the dissection reached the pylorus the ulcer was entered and it was necessary to detach the stomach at the pylorus. Inspection showed the duodenum and pancreas to be one inflammatory mass and closure of the duodenal stump would be hazardous and insecure. A Billroth II, Hoffmeister, retrocolic subtotal gastrectomy was done. The nasogastric tube was threaded into the afferent loop. The duodenal stump was closed around a No. 16 straight rubber catheter with absorbable sutures. A long tract was made to the skin and covered with omentum. The duodenal catheter was brought out through a separate stab wound; no penrose drain was inserted. The drainage from the tubes postoperatively were as follows:

	1	2	3	4	5	6	7	8	9	10	11	12
Nasogastric Tube	2200	500	1500	1100								
Duodenal Tube	125	200	225	?	500	2025	1200	1200	0			

The naso-gastric tube was removed on the fourth day and feeding started on the fifth day. The duodenal tube was clamped on the eighth postoperative day and removed on the thirteenth day. After the duodenal tube was clamped there was a moderate amount of drainage on the skin around the tube for about a week. A very slight drainage persisted for three more weeks and then stopped. The patient was discharged on the sixteenth postoperative day.

Both patients have remained well and free of symptoms since surgery.

Discussion

Duodenostomy or duodenal decompression is not a new procedure. However it was not until fluid and electrolyte replacement therapy could be accurately managed that it became practical. In the cases presented the duodenal drainage was never a problem, but others report that the drainage may be considerable. Rodkey and Welch[5] recommend the routine use of a feeding jejunostomy tube. If the duodenal drainage is large in amount they connect the duodenal tube to the jejunostomy tube.

In addition to proper fluid and electrolyte replacement, other details must be followed to avoid complications. It is suggested that large catheters or Foley catheters not be used. Absorbable sutures should be used and a tight closure of the duodenum around the catheter be made.

Medicine and its Practitioners in Mower County Prior to 1900

Nora H. Guthrey
Stewartville, Minnesota

William Carpron, a graduate of the medical department of the University of Michigan, visited Dexter and Adams in the summer of 1891. He later moved to Wells, Faribault County.

Orson A. Case, an eclectic physician, active in local eclectic medical societies in due time, practiced in various communities in southern Minnesota, probably beginning in the late eighteen fifties or the early sixties. He is said to have been the first physician, date not known, in the village of Sanborn, Redwood County; he again practiced in Sanborn in the period 1886-1893. By 1864, presumably after his first departure from Sanborn, he was practicing in Preston, Fillmore County, and apparently was an active member of the community. Thereafter he was in various other villages of that county. (See medical history of Fillmore County.) In 1870, he was graduated from the Bennett College of Eclectic Medicine and Surgery of Chicago.

By 1877, this practitioner was in Grand Meadow, Mower County, "a physician of fair ability, a graduate," but went elsewhere in the following year. Subsequently he was again in Chatfield, for in the official register of physicians of the state of 1883-1890 he was listed as in that village, practicing under the Affidavit Law of 1887. In a later edition of the register, he was enrolled, without address, as the possessor of an exemption certificate. His name did not appear in the first issue, in 1906, of the directory of the American Medical Association.

Willis Frederick Cobb (1847-1932) provides an excellent example of the finest type of country doctor in the pioneer days of Minnesota and Iowa. His career spanned fifty-eight years of rural medicine at the border of those two states. He lived at Mona, Mitchell County, Iowa, from 1874 until 1895, when he moved to Lyle, Mower County, Minnesota, one mile north of the interstate line.

Willis F. Cobb was born in Limington, Maine June 14, 1847, the only son of Joel Cobb and Abigail O'Brien Ellis Cobb. The family lived for a time in Cornish, Maine, before moving to Rutland, Wisconsin. In Wisconsin, Willis Cobb attended district school, the Evansville Academy and the University of Wisconsin, from which he was graduated with the degree of bachelor of philosophy in 1870. He was graduated from the Chicago Medical College in 1874, and a month later began practice in Mona, Iowa. On April 30, 1871, he was married to Abbie C. Mason, of Rutland, Wisconsin; to this union were born four daughters—Edith A., Edna M., Ethel M., and Enid H.

In his early years of practice, Dr. Cobb made his country calls by horse and buggy in the summer, on horseback in the spring mud, and by sleigh in the winter snow. He used sleigh bells of distinctive tone which the farmers all recognized and by which they often could locate him in case of emergency. The sound of the bells was awaited eagerly by the patient, as well as by the doctor's wife, who on hearing it could know that her husband was returning home safely.

Dr. Cobb's first automobile was a red, chain-drive Buick, with which he had more than usual trouble since it did not respond to oral commands. More than one farmer lost his front gate when the little red Buick failed to heed a loud and desperate "Whoa." The doctor's family once was startled when a late supper was delayed further because the stubborn Buick crashed through the front doors and the back wall of the barn while the good doctor pleaded ever more loudly, "Whoa, whoa, whoa."

Dr. Cobb was a deeply religious man, never forgetting his religion and his God. He was deacon of the Congregational Church and superintendent of the Sunday School at Lyle. Many years after it happened, a revealing incident was reported to a member of Dr. Cobb's family. The doctor was at the bedside of a patient, and all his medical skill had been called upon without avail. The patient, in his desperation, asked, "Isn't there anything more you can do, Doc?" "Yes," the doctor replied, "there is one more thing I can do." And reverently he knelt beside the bed and offered up a prayer for his patient. The man lived. Surely the patient and the doctor must both have had abiding faith. "Such a procedure by a modern doctor would doubtless scare the patient to death."

Dr. Cobb had other resources also which he used in stubborn and difficult cases. He knew his patients and had a good understanding of psychology. He became convinced that one of his women patients was "enjoying poor health." A present-day general practitioner probably would refer such a patient to the State Mental Health Clinic, but Dr. Cobb discussed the situation with the husband, and then told the lady that he had decided to try a new treatment: He was sure that the only thing that would relieve her was a "corncob sweat." So he heated corncobs in an old-fashioned boiler over the kitchen stove and then packed them around her as she lay in bed. In a few hours, she certainly was better and felt able to be up. After that, whenever she showed a desire to take to her bed because of some vague complaint, the mere mention of a corncob sweat was enough to get her up on her feet.

Dr. Cobb was a willing worker in community affairs. Politically, he was a Republican and he served the village of Lyle as mayor, justice of the peace, and president of the school board. In Mona, Iowa, he operated a drugstore, and in Lyle was president of the telephone company. He always endeavored to keep up-to-date in his medical knowledge, by reading of the literature and by active participation in the affairs of his county medical society. He served as president of the Mitchell County (Iowa) Medical Society and of the Mower County Medical Society. Of the latter group he was also an organizer, a charter member and vice-president. He was a member of the state medical society, and of other smaller professional groups. He was interested in the organization of St. Olaf Hospital in Austin and was one of the first physicians to make use of its facilities in his practice. He served as local surgeon for the Illinois Central Railroad for thirty-five years, and was examining surgeon for many insurance companies.

Dr. Cobb was a Mason, a member of the Royal Arch, a Knight of Pythias, and a Woodman. In addition to all his professional and civic duties, he superintended the business of his farms, raised chickens, and kept a garden. He found relaxation in hunting and fishing, and playing checkers and chess.

In 1900, Dr. Cobb went into partial retirement and moved to Northfield, Minnesota, but a year-and-a-half later returned to Lyle to complete his life among his old friends. Only during the last few years of his life did he completely give up his practice and attempt to take life more easily. He died June 3, 1932. To quote from his obituary: "The reaction of this slower living and the approach of Old Age weakened him and he passed silently to the beyond." His wife survived him with two daughters, Edith, Mrs. L. O. Olson, of Northfield, Minnesota, and Edna, Mrs. N. C. Putnam, of Lyle, Minnesota. There are four grandchildren: Willis C. Olson, of Cameron, Wisconsin, Ruth Putnam, of Cedar Rapids, Iowa, Grant Putnam, of St. Paul, Minnesota, and Audrey Mae Hueken, of Minneapolis. In 1957, only one member of the immediate family was living, Mrs. Putnam, of Lyle.

Such was the career of an outstanding pioneer physician. Certainly not an "average" doctor, a much better man than the "typical country doctor," and surely a man who left a record of conscientious service, hard work, devotion to high ideals, and an abiding faith.

William Coburn practiced medicine in Austin in the nineties. At one time, about 1898, it is said Dr. W. V. Hanscom was associated with him in practice.

J. L. Conner practiced in Grand Meadow in 1894. He committed suicide in Minneapolis in 1899 because of ill health.

Hiram L. Coon was the third physician to settle in Austin and the fourth in Mower County. Born August 25, 1828, in Grafton, New York, he early was trained in farming. When he was twelve years old he came West with his family to Milton, Rock County, Wisconsin, where he attended common school and Milton Academy, and probably began the study of medicine. On graduation from Rush Medical College in 1855 (sometimes given 1854), he started medical practice in Rutland, Dane County, Wisconsin. In 1855 he was married to Miss Sarah Morton, and in 1856 came with his wife to Austin.

In Austin and locality, Dr. Coon carried on the strenuous practice of the time. In 1859 appeared the first newspaper records of county aid to the poor; in February of that year Dr. Coon and Dr. Orlenzer Allen presented bills to the county commissioners for medical attendance on the needy. In 1861, Dr. Coon removed to Northfield, Rice County, and there continued to practice medicine. He was licensed in Minnesota on October 11, 1883. His death occurred in Northfield in 1887. Dr. Coon was a member of the state medical society and of the national medical association.

J. W. Corbitt, an allopath, a graduate of the Bellevue Medical College, New York, came from Michigan to Mower County in the autumn of 1868 and settled in Le Roy. Well educated and informed, he had had considerable experience in medical practice although still a young man, and was a good physician. He remained in practice in Le Roy most of the time until his death from consumption in February, 1881.

— **Cormack** (sometimes Cormick), according to the history of Mower County of 1884, practiced in Dexter for a year, then moved to Dakota. In the medical history of Scott and Carver Counties, of the present series of articles, it is stated that "P. L. Cormack opened an office in Jordan, Scott County, in September, 1878. In the following March he moved with his family to Dexter, Mower County, where he managed a drugstore in connection with his practice of medicine." Further record of Dr. Cormack has not been observed.

Annette Corneveaux (Finn), for nine years a successful practitioner in Austin in the eighties and nineties, received a diploma from the Physio-Medical School in Indianapolis in 1887. Later she took special courses of study and did hospital work in Chicago for a year. In 1895 she was married to Dr. J. J. Finn, a former classmate. Her death occurred a few months later (February, 1896) in Austin, from typhoid fever and pneumonia. She was about thirty-six years of age at the time.

— **Cunningham** practiced in Lyle in 1896.

Gustav William Dahlquist (1874-1950), the son of Alexander Dahlquist and Wilhelmina Ecklund Dahlquist, was a graduate of the College of Medicine and Surgery, University of Minnesota, in 1893. From that year to 1898, it appears, with the exception of a period in Hayward, Wisconsin, in 1895, he practiced medicine in Adams, Mower County, Minnesota. From Adams he removed in 1898 to Cokato, Wright County. He was then a member of the Minnesota State Medical Society and presumably of county medical societies. On January 15, 1903, aged twenty-nine years and resident in Bottineau County, North Dakota, he was licensed to practice in that state. In 1904 he was practicing in Dassell, Meeker County, Minnesota. From 1907 to 1917 he practiced at Lancaster, Kittson County.

In 1917, according to an obituary, he enlisted in the United States Army; in his death certificate (1950) it was stated that he was in the armed forces from August 5, 1918, to December 4, 1918. On completion of his military service he returned to Lancaster, and a few years later removed to Fargo, North Dakota, where for ten years he was on the medical staff of the Veterans Administration. From Fargo he returned to Lancaster in the early nineteen thirties, and a few years afterward, not later than 1940, he retired from practice. Thereafter he lived in St. Paul, and in Burke, Idaho, until he began residence at the Minnesota Soldiers' Home in Minneapolis.

Dr. Dahlquist died on October 25, 1950, at the Minnesota Soldiers' Home, from hypostatic pneumonia. He had suffered from generalized arteriosclerosis and, shortly before his death, from right-sided hemiplegia. Burial was in the National Cemetery. Dr. Dahlquist was survived by six children. His wife, Elizabeth G. Duncan Dahlquist, had died the preceding winter.

Francis Emerson Daigneau (1862-1937), from 1892 until his death, was a leading citizen and physician of Austin, Mower County.

Born October 1, 1862, at Hubbardton, near Rutland, Vermont, F. Emerson Daigneau was the son of John G. Daigneau and Henrietta Dikeman Daigneau. John G. Daigneau, who was a veteran of the Civil War, was the son of Michel Daigneau, who came from France to Canada.

F. Emerson Daigneau received his preliminary education in the village school of Hubbardton and at Newton Academy, in Shorham, Vermont. Thereafter he studied at the Séminaire de Saint-Hyacinthe, in Saint Hyacinthe, Quebec, Canada, and next, making his way by his own efforts, at a medical institution in New York City. On completion of the medical course, he enrolled at the University of Vermont, from which he was graduated in medicine in 1886 with the highest honors in his class. He received the first prize given by the faculty for "general proficiency in examinations."

Dr. Daigneau first practiced medicine, for a short time in 1887, in Somersworth, New Hampshire, before coming to St. Paul, where he practiced in the sections of Merriam Park and St. Anthony. He was licensed in Minnesota on October 28, 1887, receiving certificate No. 7-B (R).

He was married March 31, 1888, to Alice Merrick of Somersworth, New Hampshire. Two of the six children of Dr. and Mrs. Daigneau were born in St. Paul. In 1892, Dr. Daigneau came with his family to Austin, where for a time he was in partnership with Dr. William L. Hollister. In his first professional cards, he announced that he gave especial attention to the electrical treatment (then new) of the diseases of women, and to eye, ear, nose, and throat work; in those years the physician often fitted eyeglasses. For many years, Dr. Daigneau carried a heavy general practice, but after 1915 he gradually limited his professional activities to office consultation and, finally, to ophthalmology. He encouraged the organization of St. Olaf Hospital and availed himself of its facilities in his practice, was an organizer of the Mower County Medical Society and a member of the Minnesota State Medical Association and the American Medical Association.

An intellectual man of keen wit and kindly humor, Dr. Daigneau served his community well. He was for many years a member of the board of trustees of the public library of Austin. He possessed an unusually fine private library, both general and medical, and he is remembered for his diversified interest in scientific knowledge. One of his hobbies was the study of mushrooms; his friends recall that he gathered and classified the fungi of this order that appeared on the greens of the local golf course. He was interested in golf when the game was practically unknown in Austin, and to his efforts the organization of the golf club of Austin was due. He was instrumental also in founding the Cosmos Club of the city and was a member of the Royal Arcanum Society.

When Dr. Daigneau died, December 10, 1937, he was survived by his wife and by six children: Donald V. and Ralph H., of Austin; Kenneth S., of New York; Maurice, of Cleveland; Marcia L. (Mrs. P. H. MacFarlane), of Chisholm; and Elizabeth A. (Mrs. T. E. Linnihan), of Everly, Iowa. Mrs. F. E. Daigneau died March 8, 1952, and Ralph H. Daigneau, September 18, 1955. In 1957 there were living of the family, Donald V. Daigneau, well known in business enterprise in Austin, and his two sisters, Mrs. MacFarlane and Mrs. Linnihan.

F. A. Davis came to Austin about 1871, remained a year or so, and removed to Lenox, Massachusetts. Much later another Dr. F. A. Davis, with whom the former sometimes has been confused, was licensed in Minnesota, in 1903, and practiced in Freeborn, Freeborn County.

F. C. Davy in the spring of 1880 came to Le Roy and became a partner of Dr. G. M. Allsdurff. After about one year the partnership was dissolved and Dr. Davy left for Davenport, Iowa, where he became chemist in a glucose factory. Afterward he went to New York, where he received an appointment as a railway surgeon. In 1884 he was a chemist in a salt refinery in New York.

— **Dillon,** formerly of Minneapolis General Hospital and the Massachusetts General Hospital, opened an office in Austin in 1895. Reference to official medical directories indicates that the only Dr. Dillon in the state in that period was a Dr. Phillip F. Dillon (R) of Minneapolis, a graduate in medicine in 1886.

William M. Dodd (1853-1883) was for a short time in Austin and later in Brownsdale in the early eighties. Born in Cortland County, New York, December 20, 1853, he was the eldest of the three children of Isaac Dodd and Margaret Johnston Dodd, who in the spring of 1855 opened a farm in Kalmar Township, Olmsted County. In 1862 Isaac Dodd was married to Helen Ranson, a relative of the Ranson family of Dodge County, three members of which have been well-known members of the medical profession of Minnesota.

William Dodd, after attending the district school near his home, studied academic branches at Niles Academy in Rochester and medicine under Dr. Hector Galloway of that city, preliminary to formal medical training. In March, 1880 he was graduated from the Chicago Medical College, and for the next three months practiced medicine in Byron as locum tenens for Dr. Isaac Hall Orcutt. From Byron Dr. Dodd came to Austin and soon after to Brownsdale. He carried on an extensive and successful practice in both Mower and Freeborn Counties until his health failed. An attack of lung fever in August, 1882, was followed by tuberculosis. In January, 1883, with his wife, Nona Hitchcock Dodd, to whom he had been married at Milan, Minnesota in July, 1880, he went to Napa City, California, the home of his wife's parents, seeking a beneficial climate. The only child of the young couple, a little boy, died en route west. Dr. Dodd died at Napa City on April 20, 1883.

E. Dudley has been mentioned as having been in Mower County, and possibly in Freeborn County, in 1887. Information about him has not been available.

William Edwards arrived in Taopi, Mower County, about 1877 and is said to have practiced medicine there until about 1881, when he removed to Dodgeville, Wisconsin.

J. W. Eighmy (sometimes misprinted Eryhmy) was an eclectic practitioner of medicine and surgery in several different villages of Fillmore County for five or six years before he settled in Brownsdale, Mower County in 1871.

In 1868 he was in Fillmore village in partnership with H. D. Dain in a thriving drugstore. On August 23, 1868 he was married to Mary J. Priest, the daughter of a pioneer farmer in Harmony Township. In 1869 Dr. Eighmy was one of the founders and the first secretary of the Fillmore County Eclectic Medical Society.

In Brownsdale he practiced medicine for a few years and placed on the local market "Dr. Eighmy's Magic Cure for Rattlesnake Bites," and all other bites, of his own compounding, at one dollar a bottle. In the spring of 1874 he left for California, where he died a few years later.

Ellen M. Backus-Fairbanks was born Ellen M. Backus in Royalton, Windsor County, Vermont, in 1834. She was married to Alonzo Fairbanks in Vermont and came with her husband to La Salle County, Illinois, in 1855, thence to Otranto, Mitchell County, Iowa, and in 1861 (sometimes given 1859) to Austin, Mower County.

For some years Mrs. Fairbanks had been interested in the profession of medicine, and in Austin she studied with Dr. Samuel P. Thornhill (1821-1879; in Austin from 1869) as preceptor for a year or more before entering medical college. In 1881 she was graduated from the Woman's Hospital Medical College of Chicago. The Mower County history of 1884 contains the statement: "Her professional career has established the fact that women in the school of medicine may successfully compete with the opposite sex." Armstrong noted that she was a popular physician and had a fair-sized practice in Mower County.

Dr. Fairbanks received Minnesota license No. 529 (R) on December 31, 1883. She was admitted to membership in the Minnesota State Medical Society in 1885. Her death occurred in 1887. Later, Alonzo Fairbanks was a resident of Blooming Prairie, Steele County.

Charles Edward Fawcett, newly graduated in medicine from Northwestern University, practiced medicine three months in Austin in 1893 before settling perma-

nently in Stewartville, Olmsted County.

Charles E. Fawcett was born on October 13, 1869, a son of John Henry Preston Fawcett and Emily J. Wooldridge Fawcett, both of whom were members of early pioneer families in southern Minnesota. Charles Fawcett was educated at the public schools of Marion, at Darling's Business College, Rochester, and at the Winona State Teachers College. After teaching rural schools for two years, he began the study of medicine with Dr. Horace H. Witherstine, of Rochester, in the summer of 1891; that autumn he matriculated at Northwestern University, from which he was graduated on April 24, 1893.

After his initial practice in Austin, Dr. Fawcett took up residence in Stewartville, where he was in active practice until his death on December 8, 1939. A detailed biographical sketch of this honored citizen and physician appeared in a history of medicine in Olmsted County in this series.

Fannie Gray Kimball Fiester (1866-1938) was in practice in Austin from 1893 to the day of her death.

Born May 6, 1866 in West Randolph, Vermont, Fannie G. Kimball received her early education in the city of her birth. She was graduated in 1891 from the Woman's Medical College of Northwestern University and in 1893 received the degree of doctor of medicine from the Hahnemann Medical College in Chicago. She served her internship in the Iowa State Hospital at Independence, Iowa, and immediately afterward began medical practice in Austin. Her marriage to Mr. Fiester, a grocer, took place in Austin.

Dr. Fiester (then Kimball) took an active interest in the organization of St. Olaf Hospital and was one of the first physicians to utilize the facilities of the hospital in her practice. She was one of the early members of the Mower County Medical Society which was founded a few years later.

For a year or more around the turn of the century Dr. Fiester took into partnership in practice Dr. Emma Adeline Keeney, who came to Austin at that time from Spring Valley. Dr. Keeney left Austin about 1903, it is believed.

Dr. Fiester's death occurred suddenly on May 6, 1938.

A. A. Finch may have practiced medicine in Mower County in the nineties, but it seems more probable that he was in Freeborn County, or Steele County, or both. In the history of medical practice in Dakota County he is mentioned as having been in Blooming Prairie, Steele County in 1896. He was present at a meeting of the Southern Minnesota Medical Association in 1898.

J. J. Finn practiced in Austin in 1895 and 1896. In 1895 he was married, in Austin to Dr. Annette Corneveaux of that place, a former classmate. As stated previously, Dr. Corneveaux Finn died in February, 1896.

— Forward (or Faward?) came to Brownsdale in 1884. His stay there probably was brief. It is believed that he was the "Dr. Faward" mentioned as having been in Brownsdale at about that period.

William A. Frazer (sometimes seen Fraser) was for many years, beginning in the period 1885-1888, a well-liked physician and surgeon in Lyle, Mower County.

Born in Bedford, Bedford County, Pennsylvania, August 5, 1850, William A. Frazer was a son of William Frazer and Hannah Davis Frazer. In 1861 he accompanied his parents to Illinois and in 1868 to Arkansas. His mother died in 1878, his father, in 1885.

After obtaining his early education, W. A. Frazer entered the University of Kansas City, Missouri, from which he was graduated in medicine in 1886. One account states that he first came to Lyle in 1885, but soon left to continue his medical training; another, that he settled permanently in Lyle in 1888. It appears that he first practiced medicine in Blooming Grove, Lynn County, Kansas, before coming to Minnesota. In 1890, 1896, and 1900 he took graduate medical courses in Chicago.

Dr. Frazer received Minnesota license No. 1362 (R) on April 15, 1887. He was one of the founders of the Mower County Medical Society, once its president, and was a member of the Minnesota State Medical Association and the American Medical Association. In Lyle he served as justice of the peace and as village health officer. He was a member of various fraternal organizations, among them the

Masons, the Knights of Pythias, and the Modern Brotherhood of America. Politically he was a Prohibitionist. Born a Quaker, in Minnesota he attended the Congregational Church.

On February 3, 1875, William A. Frazer was married to Viola C. Johnson, of Hindsville, Arkansas. Dr. and Mrs. Frazer had six children, four of whom were living in 1911. In that year May was a student at Oxford University, England; Ray was in Minneapolis; J. D., in the insurance business in Lyle; and William M., a student at the University of Minnesota.

After leaving Lyle, date not known, it is said that Dr. Frazer practiced medicine in Minneapolis.

J. P. Freeman was born in Freeborn County, Minnesota, in 1876, and in due course was graduated in medicine from the University of Illinois. He is said to have practiced in Grand Meadow, Mower County. There is record that he practiced at Emmons, Freeborn County, and also at Glenville, where he had a drugstore. In 1910 he was listed as a member of the Freeborn County Medical Society. In 1927 he settled in Albert Lea.

Willard Wheeler Freeman practiced medicine in Minnesota from 1878 to 1904, the last five years in Grand Meadow, Mower County. Recent information to Guthrey from members of Dr. Freeman's family serves to correct and enlarge the brief account that was given in the medical history of Houston County.

Willard W. Freeman was born October 4, 1839, at Albion, Maine, where he spent most of his childhood. At the beginning of the Civil War he enlisted in the Union Army, but because of a physical disability could not be accepted, to his keen regret. After completing his preliminary education he enrolled at Dartmouth College, Hanover, New Hampshire, from which he was graduated with highest honors in 1864. Thereafter he studied law, was admitted to the bar, and entered the law office of Judge Drummond in St. Louis, Missouri. He also taught school, and for a few years (1868-1872) was president of Whitman College at Walla Walla, Washington.

He was married in 1873 at Portland, Oregon to Nancy Nichols of Taunton, Massachusetts. There were three children of the marriage, two daughters and a son.

In 1877 Willard W. Freeman was graduated from medical college in Philadelphia. In Polk's directory for 1904, he is listed as a graduate (1877) from the University of Medicine and Surgery (Eclectic), Philadelphia; elsewhere, as from the University of Pennsylvania.

Dr. Freeman began his initial medical practice in 1878, in Benson, Swift County, Minnesota, and remained there about five years. In 1883 he removed to Anoka, Anoka County, which for ten years was the family home and the scene of his practice. On December 31, 1883, under the Medical Practice Act, he received certificate No. 591-1 (R), "license by examination." In 1893 Dr. Freeman, with his family, settled in Caledonia, Houston County. His offices were over Belden's Drugstore. In this village Dr. and Mrs. Freeman recognized the need for a public library, and "with 300 donated books opened a library in the old fire hall on Main Street, a meager thing but a start."

In 1898 Dr. Freeman sold his practice in Caledonia to Dr. Da Costa Rhines and moved to Grand Meadow, Mower County, where he had bought the practice of Dr. D. F. O'Connor, who had been in the village since about 1893. Here his offices were over Greening's Bank. In the years in Grand Meadow Dr. Freeman was physician and surgeon for the Chicago, Milwaukee and St. Paul Railway Company. In 1900 he was admitted to membership in the Minnesota State Medical Society, and, subsequently, he was one of the organizers of the Mower County Medical Society, at a meeting in Austin.

In 1904 Dr. Freeman and his family left Minnesota for Colorado where, in Eads, he served as county physician and carried on private practice until his death. He died April 13, 1912 at Fowler, Colorado after a short illness, at the age of seventy-three. He is buried at Olney Springs, Colorado. Mrs. Freeman died on February 12, 1923, at Denver, Colorado.

In 1957 there were living, of Dr. Freeman's family, his son Eliot N. Freeman, an attorney-at-law in Denver, Colorado; and two daughters, Faith (Mrs. Melvin Gipe), of Salinas, California, and Mary (Mrs. Clinton D. Scott), of Glendora, California.

A grandson, Eliot N. Freeman, is a physician in Whittier, California. Dr. W. W. Freeman's children recalled vividly their father's accounts of the hardships of the early physicians: bad weather, bad or no roads, and paucity of conveniences and of professional equipment.

J. V. Frost, as noted by Armstrong, practiced medicine in Lyle for a few months in 1875. A Dr. J. V. Frost, probably the same man, was in Concord, Dodge County, in January, 1884. He announced that he specialized in chronic diseases, and he gave lectures to the public on mesmerism, marriage, and various other subjects. When it appeared that he could not pay the rent for the lecture hall, he left town abruptly.

E. S. Gibbs, according to one source, practiced medicine in Le Roy in 1869. If so, he went on at once into Freeborn County. There is record that E. S. Gibbs studied medicine with Dr. A. C. Wedge of Albert Lea, was graduated in 1869 from the Cleveland Medical College, was admitted to membership in the Minnesota State Medical Society in 1870, and practiced medicine in Geneva, Freeborn County, for a few years.

Otis W. Gibson, son of Otis L. Gibson, an eminent physician of the town, was born at Wellsboro, Tioga County, Pennsylvania in 1839. He was graduated from the College of Physicians and Surgeons, New York City, in 1860, and practiced in Wellsboro the following year. In 1861 he enlisted in the United States Navy as assistant surgeon and was assigned to the United States Warship *Alabama,* of the South Atlantic and West Indies Squadron. When in 1863 he left the Navy and became an assistant surgeon in the United States Army, he was stationed at Bedloe's Island in New York Harbor where he was virtually in charge of the medical department of a camp for convalescents. Subsequently he was appointed post surgeon at Fort Hamilton and Fort Lafayette, also in New York Harbor, where he won the respect and regard of superiors and subordinates. Toward the end of 1866 he left the service, and in February, 1867, he came to Austin, Minnesota, where with the exception of one year he spent the remainder of his life.

Under the Medical Practice Act of 1883 Dr. Gibson held certificate No. 868 (R), dated April 16, 1884. He served as a state senator in 1887-1889. In 1888 he was elected mayor of Austin, an office which he held for three consecutive terms, during which he greatly furthered civic progress. For many years he was a surgeon for the Chicago, Milwaukee and St. Paul Railway Company, and just before his death he received a similar appointment from the Chicago Great Western Railway Company. He was a member of the local board of the United States Bureau of Pensions. examining surgeon for the New York Life Insurance Company, and post surgeon of the McIntyre Post of the Grand Army of the Republic, of Austin. He also served many years as county physician.

Dr. Gibson was married to Miss C. D. Farmer, a native of New York. About 1878 Dr. and Mrs. Gibson lost two little sons, Louis and Frank, who died tragically from diphtheria during an epidemic. In 1884, as stated in the county history of that year, there were two children living, a son and a daughter.

Otis W. Gibson died in Austin in January, 1896, of Bright's disease. This able pioneer physician and surgeon, loyal in all relationships, made many friends. He is remembered as being especially kind to the poor, giving them much gratuitous service, and to old soldiers and members of their families.

Charles M. Gordon (sometimes seen M. C. Gordon) came to Lyle from Montreal in 1881 and practiced there for a short time. Reputedly, he was of the "old school." His professional card announced him as a member of the College of Physicians and Surgeons of Ontario and Quebec and a graduate of McGill University, Montreal.

George W. Gray (1851-1914), a prominent member of the profession locally, came to Mower County in 1877. One writer expressed the belief that he first practiced in Taopi. Dr. Gray himself, however, wrote as follows, for inclusion in the history of Mower County that was published in 1884: "Corrected by G. W. Gray, M.D.: G. W. Gray was born in 1851 of English parentage. He came to Minnesota in 1877 and located at Grand Meadow, where he practiced in his profession until 1883, when he came to Brownsdale, where he is continuing the practice of medicine and surgery. He is a regular practitioner and a successful physician. Dr. Gray was married at Grand Meadow, October 1, 1879, to Miss Viola

F. Sebring. He is a member of the Grand Meadow A. F. & A. M. Society, and served as police justice while a resident of Grand Meadow, and is a staunch Republican."

Dr. Gray practiced in Minnesota under exemption certificate No. 65-B, dated October 11, 1883, "no report" as to medical school. He often served as a county physician, was one of the first members of the Mower County Medical Society, and a member of the Minnesota State Medical Association. In 1906, he was still in practice in Brownsdale. He may have been in Austin later, and in the last years of his life he made his home in Minneapolis, according to reports of his death. In the *Journal-Lancet* of December 15, 1914, it was stated that Dr. Gray, of Brownsdale and Austin, died "last week." In a similar account in the *Journal of the American Medical Association* of February 13, 1915, it was reported that Dr. Gray had died recently at his home in Minneapolis.

Thomas Edmund Hall, a graduate of Rush Medical College in 1875, came in that year from Preston, Fillmore County, to Brownsdale and to Austin. After a short time he left Mower County.

He was born at Preston in 1854, the son of Mr. and Mrs. Thomas Hall, who were among the earliest settlers of Fillmore County. He began medical practice in Lanesboro, and in the next twenty years practiced in many different towns in various counties of southern Minnesota: Fillmore and Mower, as stated, Martin, Wabasha, Goodhue, Winona and Houston. He held state certificate No. 781 (R), issued on January 28, 1884. In 1886 Dr. Hall returned to Lanesboro, probably from Dresbach, Winona County, and remained until about 1909, when he moved to La Crescent, Houston County. In 1910 he was living and practicing in La Crosse, Wisconsin, where he died on May 5, 1912. (For detailed account, see medical history of Fillmore County.)

A **Dr. Hanson** has been mentioned as being in Austin in the middle nineties. It is said that he was from Osage, Iowa, in Austin temporarily.

W. V. Hanscom was in Austin in the middle and later nineties, and entered into partnership with Dr. William Coburn of that city in 1898. In the official directory of 1883-1890 of Minnesota, there were listed as of Minneapolis: W. H. Hanscom, University of Minnesota 1889, certificate No. 69-B (R) July 6, 1889; and W. C. Hanscome, Rush Medical College 1884, state certificate 925 (R) May 15, 1884. These names are given here because of the possibility that one of these physicians may have been in Austin in the nineties.

Milan J. Hart (1862-1931), one of Mower County's best loved and most able physicians, practiced in Le Roy from 1895 to 1921.

Born on a farm in Dover Township, Olmsted County, Minnesota, on May 9, 1862, Milan J. Hart was one of the five children of John G. Hart and Phoebe March Hart, early settlers in Olmsted County who had come from Ashtabula, Ohio. Mr. Hart died in 1876, four of the children left home early, and Milan was left with his mother (died 1895), to whom all her life he was a kind, devoted son, to work the farm alone.

He obtained his preliminary education under difficulties; his professional training necessarily was delayed. Inspired by Dr. Augustus W. Stinchfield, then of Eyota, the boy early resolved to be a physician. He had an aptitude, even as a small boy, for attendance on the sick, a capacity which Dr. Stinchfield noted when he was called to see a close friend of the Hart family and found the lad helping the patient. He said then, "Milan, you ought to be a doctor." Years later when the young Dr. Hart was thinking about a specialty, Dr. Stinchfield said, "Take care of the mother and the child and you will be a success," and in the course of a diversified practice Dr. Hart did make obstetrics a specialty.

As soon as he could arrange his affairs, Milan Hart entered the medical school of the University of Minnesota, earned his way through, and was graduated in 1895. Soon afterward he bought the practice of Dr. H. L. Knight, who was leaving Le Roy temporarily, and began his life as a physician. In 1897, his close friend and university classmate, Dr. Melvin C. Millet, became his partner and remained with him two years before joining the Mayo group in Rochester.

On September 15, 1898, Milan J. Hart was married to Mabelle Avery, a school teacher, daughter of Mr. and Mrs. John Avery, of Le Roy. Mr. Avery, a merchant,

and his wife had come to Le Roy in 1869 from Kendalville, Indiana.

In his years in Le Roy, Dr. Hart carried a heavy general practice in village and countryside. With the coming of World War I, many physicians went into the service so that here, as elsewhere, few were left in the locality, and when the region was swept by a severe epidemic of influenza, Dr. Hart and Dr. Aaron E. Henslin, who also had settled in Le Roy in 1895, shared the work. They were not in partnership, but were friends, and both were dedicated physicians. On one day, Dr. Hart would go west, seeing the patients of both, while Dr. Henslin would go east, taking care of all. Another day, one would cover the territory to the north, the other, the communities to the south.

Dr. Hart was faithful to both civic and professional obligations. He was a member of the school board and its president for several years. At one time, he was president of the local telephone company, and vice-president of the First State Bank of Le Roy. He was a member of the Southern Minnesota Medical Association, its vice-president in 1901; the Mower County Medical Society, one of its early presidents; and of the state and the national medical associations. Perhaps he rendered no greater service than as president of the county board of health for many years.

Because of his own early struggle, Dr. Hart felt sympathetic interest in young people, especially those who had difficulties to overcome, and he quietly encouraged and helped them. Long afterward, it was learned that he had special pleasure in giving financial help to medical students who had need of it, as he had needed such help in his university days. To their credit, most of them paid him back.

After twenty-five years in Le Roy, Dr. and Mrs. Hart in 1921 removed permanently to California, first to Redlands for a year, then to Pasadena, where Dr. Hart was in practice with Dr. George E. Campbell, formerly of Wykoff, Fillmore County, Minnesota. In 1923, they returned to Redlands and there Dr. Hart practiced for the ensuing six years. Because of progressive ill health, he retired from practice in 1930. He died in Redlands on March 24, 1931, from high blood pressure and the resultant cardiac strain.

Some ten years after Dr. Hart's death, Mrs. Hart, visiting in Rochester, Minnesota, reminisced delightfully of early humorous incidents in their domestic and social life and, particularly, of some of the doctor's experiences in his first years of practice: his finding himself, while trying to answer an emergency call in a blizzard, driving over fences drifted post high with snow; his amputation of a man's leg mangled in an accident with farm machinery, the operation being performed in the kitchen of the farm home with an ordinary kitchen butcher knife, sharpened and sterilized, because his emergency kit was not at hand; and of one of his more disagreeable experiences in attempting to enforce quarantine in scarlet fever. On that occasion an indignant and uncooperative householder reported him to the State Board of Health. Dr. H. M. Bracken, then chairman of the board, replied, "If I ever found Dr. Hart remiss in his duty, I would remove him, but I never have."

Christian A. Hegge (1866-1936), who for thirty-seven years (1893-1930) was a respected citizen and a skilled physician and surgeon of Austin, Mower County, held the esteem and affection of the community.

Born on the Hegge farm, Biri, Norway, on April 23, 1866, he was the son of Mr. and Mrs. Andreas Hegge. After attending grade school and high school, he enrolled at one of Norway's best agricultural colleges from which he was graduated with the degree of bachelor of agriculture. For a year after graduation he was manager of a large farm. In that period, Dr. O. H. Hegge has said, young people in Norway had what was called "America fever," and immigration to the United States was common. Christian A. Hegge decided to try his luck in the new world, and in 1887 he arrived at Whitehall, Wisconsin, where during his first summer in America he worked for a distant relative, Mr. Ekern, a well-to-do mill owner.

In the autumn of 1887, Christian A. Hegge went to Minneapolis and registered at Augsburg College, of which Professor Georg Sverdrop, a graduate of the University of Oslo, was president. After a year at the college he went out into the Norse settlements of Minnesota selling religious books, mostly Bibles, to earn money to continue his education. In September, 1889, on the advice of Professor Breda, head of the Scandinavian Department of the University of Minnesota, and himself a graduate of the University of Oslo, Christian A. Hegge and his brother, Olav H.

Hegge, who had arrived in Minneapolis from Norway the previous day, enrolled at the University.

After two years at the University of Minnesota, C. A. Hegge and O. H. Hegge registered in the medical department of the University of Illinois, from which they were graduated with honor on April 12, 1893. In that period internship was not required, and there were few graduates who wanted to spend the necessary time and money for the purpose. The Doctors Hegge were two who recognized the importance of the additional training. Dr. C. A. Hegge served his internship, one of the first to be granted by the institution, at the Minneapolis City Hospital, and joined Dr. O. H. Hegge in practice in Austin, Mower County, in December, 1893. Dr. O. H. Hegge, on December 12, 1893, first had visited Austin, and with Dr. C. A. Hegge had made arrangements for beginning the practice of medicine there.

At that time, Austin was a county seat of 3,000 inhabitants. There were few facilities, no telephone, no paving, no electric lights, no automobiles. The country roads were dusty, muddy or snow covered according to weather and season, and over them, in those horse-and-buggy days, Dr. C. A. Hegge and Dr. O. H. Hegge soon were covering four counties in Minnesota and three counties in Iowa. They worked hard, almost day and night, and often under great difficulties. For a time in 1894 they maintained an office in Blooming Prairie, Steele County, as well as in Austin. For a considerable period, their best known fellow physicians in Austin were W. H. McKenna, A. W. Allen, C. H. Johnson, Alexander MacDonald and F. E. Daigneau. The Doctors Hegge kept abreast of medical advance by activity in medical associations, and by study and observations at hospitals and clinics both in the United States and in Europe, particularly in Germany, the Scandinavian countries, and England.

Dr. C. A. Hegge served often as a county physician and as city physician. He and his brother were the first to recognize the need for a local hospital, and Dr. C. A. Hegge gave his energies to aiding Dr. O. H. Hegge in the organization of St. Olaf Hospital, Austin, which was opened in 1896, and was a member of the first staff of the hospital. Dr. C. A. Hegge early became a member of the Southern Minnesota Medical Association, was a founder and the first secretary of the Mower County Medical Society, and a member of the Minnesota State Medical Association. He was a supporting member of St. Olaf Lutheran Church, and was active in fraternal organizations, among them the Masonic Lodge, the Knights of Pythias, and the Knights of the Maccabees. Politically he was a Democrat.

The partnership between Dr. C. A. Hegge and Dr. O. H. Hegge continued for thirty-seven years. In 1929, when Dr. Rolv S. Hegge, son of Dr. O. H. Hegge, joined the firm, in their "Hospital Clinic," Dr. C. A. Hegge, who for some time had wanted to revive his study of agriculture and horticulture, removed to his ranch in the Magic Valley of Texas, in Cameron County, near La Feria. There he raised oranges and grapefruit with enjoyment and success. He never again practiced medicine.

Christian A. Hegge was married on May 14, 1895, to Isabel Dalager, a school teacher of Minneapolis. Two daughters, Nina and Agnes, were born to the marriage. In Texas Dr. and Mrs. Hegge made their home at La Feria. Dr. Hegge died in Texas in 1936 from coronary thrombosis, at the age of seventy, survived by his wife and his daughters. When Mrs. Hegge died a few years ago, she was buried beside her husband in La Feria. In 1957 the elder daughter, Nina Hegge Vignes, still lived on the Hegge ranch.

Olav H. Hegge (1872-—) in 1960 is in his sixty-eighth year of continuous practice as physician and surgeon in Austin, Mower County.

Born in Biri Parish, Norway, on March 20, 1872, a half brother of Christian A. Hegge (*q.v.*), O. H. Hegge received his earlier education at a private school, at high school, and at Aars and Voss College, Oslo. In 1889 he came to the United States to join C. A. Hegge, who had been in Minneapolis since 1887. On his second day in Minneapolis, O. H. Hegge, with his brother, enrolled at the University of Minnesota. Better prepared academically than most students, he was prepared to write and speak English, German, and all the Scandinavian languages, and had some knowledge of French.

Together with his brother, as he has said, he "headed for the study of medicine," and in the autumn of 1892 both O. H. Hegge and C. A. Hegge entered the medical department of the University of Illinois, from which they were graduated with

honor on April 12, 1893. Dr. O. H. Hegge at that time had spent four years in continuous study in this country and he was anxious to return to Minnesota to practice medicine because a great many of his native countrymen by then had settled in this state. He served his internship at Bethesda Hospital, in St. Paul, and on December 12, 1893, began the practice of medicine in Austin, in partnership with Dr. C. A. Hegge.

Those were still pioneer days, in the difficulties of medical practice, lack of facilities and conveniences and in the hazards of travel at all hours and in all seasons over unimproved roads. The lives of Dr. O. H. Hegge and his brother were a saga of unremitting hard work and devotion to their profession. Dr. O. H. Hegge, again in common with Dr. C. A. Hegge, was a constant student of medicine, in the medical literature, in medical societies, and in attendance at clinics in this country and in England, Germany and the Scandinavian countries.

One of the chief services Dr. O. H. Hegge rendered his city and community was the founding and initial financing of St. Olaf Hospital, opened in Austin in 1896. In the establishment of the hospital, of which he was the first surgeon, he gives much credit to Dr. C. A. Hegge and other physicians of Austin and to the congregations of St. Olaf Lutheran Church and other Lutheran churches of the vicinity.

Dr. O. H. Hegge was the chief organizer of the present Mower County Medical Society, which now has functioned successfully for more than five decades. He long has been an active member of the Minnesota State Medical Association and the American Medical Association. In 1944 he was honored as a member of the Fifty Year Club of the state medical association, at a meeting in Rochester. In 1947 he was a guest of honor, with Dr. A. E. Henslin, Le Roy, and Dr. G. J. Schottler, Dexter, at a dinner given in Austin by the Mower County Medical Society in recognition of the more than fifty years of service in his county, of each of the honored guests.

In past years, Dr. Hegge was city physician and county physician. He has been local surgeon to the Milwaukee, St. Paul and Pacific Railway Company for forty-five years. During World War I, from the first day to the last, he was Chairman of Medical Advisory Board No. 20. In private practice he long has been president of the Hospital Clinic. He is a co-founder and a director of the Austin State Bank, and is president and a director of the Austin Savings and Loan Association, with more than sixty years of service in the institution. Dr. Hegge is a supporting member of St. Olaf Lutheran Church. When Austin was struck by a disastrous tornado some years ago, in which the church building was destroyed, Dr. Hegge was appointed chairman of both the finance and the building committees, which built and fully financed the new edifice, the largest Protestant church in the city. He is a Republican, and the member of civic and fraternal organizations, among them the Kiwanis Club and the Masonic Lodge. He finds recreation in travel, reading, and fishing.

Olav H. Hegge was married on April 20, 1898, to Stella L. Johnson, a fine and competent woman, a daughter of Mr. and Mrs. Seymour Johnson, early settlers in Austin. Three children were born to Dr. and Mrs. Hegge: Rolv S. Hegge, who died in 1955; Milda L. (Mrs. L. H. Williams), who died in 1936; and Valfrid M. (Mrs. Theodore Heimark). Mrs. Hegge died fifteen years ago. In 1957 there were eight grandchildren, four boys and four girls, all well educated and well established in life.

Dr. Hegge has said that he planned his life span as follows: First, thirty years for education; second, thirty years for very hard professional work; third, thirty years for moderate work, the evening of life, provided that he should live to become ninety years old. He thought, "We should try to lenthen the productive period of our lives and always remember that 'good nature is good business.' " His life-long motto has been, "Expect the best, prepare for the worst, take what comes."

A brief note is given here about the late Dr. Rolv S. Hegge (1902-1955) who, although not in the group with which this history primarily is concerned (physicians who entered practice prior to 1900), played an important part in the practice of medicine and surgery in Austin in association with his father and his uncle.

Rolv S. Hegge was born in Austin, Minnesota, on July 2, 1902, the son of Dr. O. H. Hegge and Stella L. Hegge. He was graduated from the Austin High School, St. Olaf College, in Northfield, Minnesota, and, in 1928, from the University of Minnesota with the degree of doctor of medicine. He served his internship at St.

Mary's Hospital, Duluth, and in 1929 began the active practice of medicine with his father and his uncle in Austin, as a member of the Hospital Clinic. In 1950 Dr. R. S. Hegge was taken ill with multiple sclerosis, a disease of unknown causation which affects relatively young persons. This disease afflicts more than 250,000 persons in the United States; and at present, satisfactory treatment is not available. Dr. R. S. Hegge served successfully in the Hospital Clinic for twenty-one years from April, 1929, into 1950. By the latter year he was handicapped so severely that he had to resign. Dr. Hegge was a high-ranking Mason, a Knight Templar, and a member of the Presbyterian Church.

Rolv S. Hegge was married on April 7, 1930, to Dorothy J. Botz. To this marriage three daughters were born. When Dr. Hegge died, December 4, 1955, his wife and the children survived him. Dr. Hegge was a kind husband and father, a devoted son. He was respected and esteemed in his community. He treated all alike, rich and poor, and never shirked his duty. His guiding prayer was:

> Lord grant that mine ears be swift to hear
> The cry of those in pain.
> Give to my tongue the words that bring
> Comfort and strength again.

Aaron E. Henslin (1865-1950), of Le Roy, was a valued and progressive physician and citizen of Mower County for nearly sixty years.

Born on June 20, 1865, on a farm near Racine, Mower County, Aaron E. Henslin was the son of Frederick Henslin and Ernestine Weckworth Henslin. Mr. and Mrs. Frederick Henslin were natives of Germany who came to America as children with their respective parents. Both families first settled at German (New Baden), Wisconsin. The Henslin family moved to Brownsdale, Mower County, Minnesota, in 1859, and to Racine in 1864. Mrs. Henslin died in 1891; Mr. Henslin moved to Sargent, Mower County, in 1901; his death occurred there in 1903. There were nine children, of whom seven were living in 1924.

Aaron E. Henslin, the second eldest child, received his early education in the schools of Racine, and at the high school of Spring Valley, Fillmore County. In 1891, he received the degree of doctor of medicine from the College of Physicians and Surgeons of Keokuk, Iowa, and began the practice of medicine at Adams, Mower County. In the next four years, he continued his medical education: at Rush Medical College, at the Chicago Polyclinic, and at the Milwaukee Medical College, from which he was graduated in 1895. At the last-named school he was an instructor in anatomy. Thus, well prepared for continuation of practice, he settled permanently in Le Roy in 1895.

Those were still years of pioneering, and Dr. Henslin, with his fellow physicians, experienced all the hazards and difficulties of the time: limited facilities, no local hospitals, bad roads, torrential rains, severe winter weather. An instance of extreme test of endurance was the severe epidemic of influenza in 1918 when Dr. Henslin and his close friend, Dr. Milan J. Hart, who also had settled in Le Roy in 1895, gave valiant service, well remembered in the community. They shared the burden, each covering a large territory: on one day one would cover the territory to the north, the other, the region to the south; and on the following day one would go east, the other, west, each seeing the patients of both.

Dr. Henslin served in various civic capacities, notably as president of the village council, president of the school board, and member of the library board. Before 1900 he started operation of the telephone system which later became the Le Roy Telephone Company, with numerous exchanges in near-by towns. He was a member of fraternal organizations, among them the Benevolent and Protective Order of Elks, of Austin, the Modern Woodmen of America, and the Independent Order of Odd Fellows, and was medical examiner for other groups. In politics he was an Independent Republican. When time permited, he found recreation in chess, and in hunting and fishing.

His professional record is a distinguished one. In addition to a widespread general practice of medicine and surgery, he was at different times a county physician, health officer, and for twenty years county coroner. He was associated with St. Olaf Hospital, Austin. He was an organizer of the Mower County Medical Society, twice its president, and for thirty years continuously, its treasurer. In 1937 Dr. Henslin was honored at a social function given by the people of his town and community. When, on March 26, 1947, he was honored by the Mower County Medical Society,

with Dr. O. H. Hegge and Dr. G. J. Schottler, for his fifty-six years of service as physician and surgeon in Mower County, he received additional tribute for his service as treasurer. Dr. Henslin was an active member of the Southern Minnesota Medical Association, the Minnesota State Medical Association, and the American Medical Association.

Aaron E. Henslin was married on June 1, 1905, to Mary Louisa Pinckney, daughter of Mr. and Mrs. James Pinckney of Racine. Mr. and Mrs. Pinckney came to Racine from Syracuse, New York, in 1867. Mrs. Henslin took an able part in the social, church and civic life of Le Roy. At various times she was president of the local History Club, president of the Library Association, a member of the park board, and chairman of the local Ladies Republican Club.

Dr. and Mrs. Henslin were the parents of two sons: Robert Frederick, who died in youth, and Merrill Edgar. Mrs. Henslin died on November 10, 1940. When Dr. Henslin died March 25, 1950, at Cresco, Iowa, he was survived by his son, Dr. Merrill E. Henslin, then of Cresco, and by two sisters.

Dr. Merrill E. Henslin later returned to Le Roy to practice, and subsequently removed to Garden Grove, California, where, in 1956, he was a practicing surgeon.

William L. Hollister (1837-1921) was a prominent physician and citizen of Austin and Mower County for fifty-three years. Truly a pioneer, he experienced all the difficulties and hardships of medical practice in the decades before the turn of the century. "He served this community with a devotion which knew no reserve, and a kindness which never failed."

Born on January 9, 1837, in Sharon, Schoharie County, New York, William L. Hollister was one of the six children, four sons and two daughters, of Luther Hollister (1802-1888) and Jane Onderdonk Hollister (1811-1892). The Hollisters of this branch were descended from Lt. John Hollister, who came from England to Connecticut in 1642. Members of the family were prominent in Colonial affairs, and several served with the Colonies in the American Revolution. The first Hollister to settle in New York State in 1800 was the father of Luther Hollister.

Before William L. Hollister was two years old, the family moved to a farm in Montgomery County, New York. Here he grew up, worked on the farm in summer and attended district school in winter until he was eighteen. He then entered Fort Plain Seminary, taught district school for two years after graduation, and at the age of twenty-two began the study of medicine under Dr. A. H. Knapp, who later for many years was superintendent of the hospital for insane at Ossawattoma, Kansas. William Hollister next took a "full course of medical lectures" at the Albany Medical College, from which he was graduated in 1861. He first practiced medicine in Stuyvesant, New York, and later in Kingston, where for two years he was assistant surgeon in the office of the provost marshal.

On January 9, 1862, William L. Hollister was married in Coxsackie, New York, to Mary M. Beatty (1837-1929), daughter of Mr. and Mrs. William Beatty of that place. In 1868, Dr. and Mrs. Hollister came to the village of Lansing, Mower County, and in 1871 to Austin, to the residence on South Main Street that was their home for the remainder of their lives. They were the parents of three children: Clarence and Lansing O., who were born in New York, and John Francis, who was born in Lansing, Minnesota. Early in 1878, all three boys were stricken with diphtheria: Clarence, the eldest, then about twelve years of age, died on January 13, 1878. A few years later, on November 13, 1882, John Francis, the youngest, then twelve years old, died tragically from tetanus, the result of an accidental gunshot wound of the right hand and arm received while hunting.

In 1880, Dr. Hollister was admitted to the Minnesota State Medical Society, one of the earliest members in Mower County. After 1883 he practiced medicine under an exemption certificate. Early interested in medical organization, in February, 1880, he was one of the physicians of the county who were instrumental in organizing a medical society in which the physicians of Freeborn, Steele and Fillmore Counties were invited to join. The resulting organization, called "The Southern Minnesota Medical Society," perhaps was the forerunner of the Southern Minnesota Medical Association (founded in 1892) and possibly was the "old Mower County Medical Society" of which mention has been noted. Dr. Hollister was a founding member of the present Mower County Medical Society. About 1905 he retired from active medical practice.

An ardent Republican, for many years Dr. Hollister took an active part in political and civic affairs, and he retained his interest in them to the end of his life. In 1882 he was elected state senator from his district and in this capacity was influential in procuring the passage of the Medical Practice Act of 1883. He worked to perfect the laws concerning infectious diseases, and aided in the enactment of many other laws relating to public welfare. In 1883, he resigned his senatorship to accept appointment as a United States revenue inspector. A year and a half later he resumed medical practice in Austin and also his activity in civic life. During his years in Austin he served as a member of the city school board, for many years as a county commissioner, and as examiner on the local board of the United States Bureau of Pensions. At various times, he was coroner and a county physician. In 1907, he again was elected to the state legislature, as representative.

Among the fraternal organizations of which he was a member were the Masonic Lodge and the Austin Lodge of the Benevolent and Protective Order of Elks; of the latter he was a charter member and one of the first officers. The Hollister family attended the Congregational Church.

On February 25, 1921, Dr. William L. Hollister died at his home from acute pneumonia, after an illness of six hours. He was survived by Mrs. Hollister and a son, Lansing O. Hollister. Mary Beatty Hollister died December 28, 1929, from the infirmities of old age.

Lansing O. Hollister, the last member of the immediate family in this region, it is believed, died in Austin a few years ago. He was married on November 27, 1889, to Mattie E. Messersmith of Austin; at that time he was assistant cashier in a bank in Morris, Minnesota. A later marriage, about 1912 (?), was to Mrs. J. M. Thomas, of Austin. He then was employed as bookkeeper at the Hormel Packing Plant; he and his wife made their home with Dr. and Mrs. Hollister. An old scrapbook of the Hollister family contains many interesting newspaper clippings concerning various members of the Hollister and the Beatty families, some of whom had visited, or had lived for a time, in Austin.

E. P. Hudson "came to Austin about 1891."

— **Huffman**, an eye and ear specialist from St. Louis, practiced in Austin for a few months in 1863. It seems almost proved that this man was the Dr. Huffman, apparently an itinerant practitioner, who was in Preston, Fillmore County, early in 1863, there exhibiting, according to the *Preston Republican,* "much skill in the way of restoring loss of sight and hearing. Those afflicted with diseases of the eye and ear would do well to call at the Minnesota House and consult him."

William R. Hunter (1813-1874), physician, surgeon, and dentist, spent about eighteen years in Minnesota during an interesting period in the history of the state. Born on October 14, 1813, at Strong, Franklin County, Maine, he was graduated from Bowdoin College, Brunswick, Maine, in 1844, and from Jefferson Medical College, Philadelphia, in 1848. Dr. Hunter came to St. Cloud, Stearns County, Minnesota, in 1856. His residence in the state was broken by his return to Maine, where he spent the winter of 1865. There is record that on his return to Minnesota he was on the medical staff of the Northern Pacific Railway, and that in 1871 he traveled the lines between St. Cloud and Brainerd, checking on the health of the railway employes. In 1872, it is said, he was physician for the Pembina branch of the railroad, and in that period he moved from Glyndon to headquarters at Red Lake Crossing.

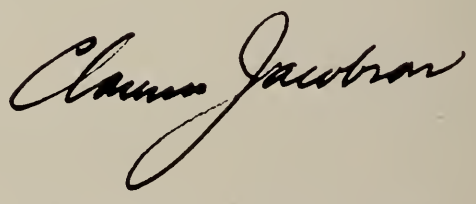
Although local accounts agree as to season of Dr. Hunter's arrival in Brownsdale, Mower County, and length of residence, they differ as to year. The verified date of his death, April 24, 1874, however, establishes the time of arrival as the autumn of 1873: "his death occurred there the following year, after an illness of a few days from inflammation of the lungs."

(To be Continued)

President's Letter

OPPORTUNITY FOR ACTION

We are now in the early aftermath following a momentous election. A period when the winners will re-assemble their forces to attempt the implementation of their promises to the people. Congress, when convened, will surely reconsider many measures relating to the health care of our people.



The voluntary approach to meet the health needs of our nation has gone forward with surprising rapidity. Competition has stimulated Blue Shield and Blue Cross plans to improve their contracts. Uniform programs by Blue Shield, adequate to meet the demands of the National market in negotiating contracts with government employees, union labor, and employer groups, were strongly advocated by Blue Shield leaders at the annual Program Conference in Chicago in October.

Medicine scored a respite in the passage of H.R. 12580 for the health care of the aged. This measure permits temporary increases in federal grants to help with the 2,400,000 persons on old age assistance and with matching funds to the states for financing the health care for an estimated 10,000,000 aged who are not on relief but who do not have sufficient income to meet the cost of illness. It is already evident that the opportunists, and some well meaning people, will endeavor to prevent the implementation of H.R. 12580 in many states.

Cabinet member, Arthur S. Flemming, Secretary of Health, Education and Welfare, in a strong address, said past experience in the Department of Welfare indicates that states will be quick to act. This was proven twenty-five years ago when forty-one states responded to O.A.A. legislation within one year.

Our duty is clear. We must appeal to our state legislators, urging them to activate the new program. Minnesota offers a better than average opportunity for its usefulness and success.

Our attention was also called to unfinished business. Many aged desire to *prepare* for a crisis. This laudable desire, a fundamental ingredient in our American way of life, cannot be ignored. We are indeed at the crossroads in this controversy in caring for the aged. "A voluntary plan helping those who wish to *prepare* for a crisis is the key." It is significant that the citizens of our country wish to give the aged the opportunity to help care for themselves. The Ways and Means Committee, the Finance Committee and finally the Congress, our duly elected body, have so indicated. America can and has progressed on this voluntary plan, "the freedom plan." Compulsion leads to confiscation which ultimately leads to complete containment, slavery.

President, Minnesota State Medical Association

Arthur H. Wells, M.D.

THE ART OF MEDICINE

The art of medicine is in need of scientific study. This was the theme of Dr. George Engel, Professor of Psychiatry from the University of Rochester, when he spoke at a University of Minnesota Medical School convocation, July 20, 1960.

Doctor Engel said that the true clinician has something in his bedside manner, in his concern for, his friendship toward, his counseling and comforting of his sick patient that influences the course, severity, duration of, and even recovery from the disease; that the diagnostic and therapeutic factors inherent in the doctor-patient relationship can and ought to be the subject of scientific inquiry.

However, in order to begin a scientific investigation, disease must be redefined in a broader sense. In this broad sense, the diseased state is a condition of life defined by disturbed adjustment and altered structure and function in relation to the state of health. The stresses that affect the state of health and cause disease can be produced by diverse and multiple agents. Significant stresses can be positive, something happening to the person, or negative, something *not* happening to the person.

Doctor Engel discussed grief as a disease to show how the inter-personal relationships affect both health and disease. For health each individual requires human contacts, the number and variety required varying from person to person and according to his specific ability to react to these human contacts. Grief as a disease is most commonly caused by the loss of a personal human contact, although at times loss of a job, failure to achieve a goal, loss of money, may also be pathogenic.

Like any other disease, grief has a predictable natural history. There is first a state of shock in which the person is unable to respond to, even to accept the loss of the loved one. He may not respond normally to familiar situations. The shock is followed by a variable period of emotional release, sometimes controlled, sometimes not. At times, the person reciprocates between shock and emotional release. These give way to a continual preoccupation with the dead, where the suffering one feels that he must remember the lost because no one else will, because the others have forgotten already. Actual physical symptoms develop. A predisposition to organic disease is formed. Organic diseases such as coronary thrombosis, stroke, ulcer, cancer, diabetes, arthritis, cholecycitis, are initiated when other causes have created a predisposition. The physical symptoms of the induced diseases may confuse the real cause of the illness.

Psychologic reactions follow: Depression, guilt feelings, hostility, and refusal to enter normal activity. They may occur sequentially or simultaneously and may be of long or short duration.

When feelings of helplessness and hopelessness develop, the organic and psychologic manifestations of grief become extreme, debilitating and even fatal. On the other hand, when feelings of helplessness and hopelessness are not present, these grief manifestations may be short and mild or even absent from the course of the disease.

Recovery begins with a gradual realization of the unreality of the grief behavior and is complete when readjustment is made to the remaining human contacts.

Treatment is based upon a therapeutic replacement, by the physician (or clergyman) or by something he does or says within the doctor-patient relationship, substituting in part for the lost loved object.

Grief cannot be prevented—death is the price we pay for life—but the physician can often prevent the pathologic consequences of grief by psychological preparation for this loss of a loved one and by early recognition and treatment of grief.

This analysis of grief as a disease clearly identifies three views of medicine that are becoming increasingly important today:

1. The mantle of the physician includes more than the laboratory and the pharmacy, it includes the art of medicine, the psychosomatic approach and the bedside manner.

2. Any training of physicians to interpret disease solely through the eyes of the laboratory and to treat disease solely through the hands of the pharmacy is scientifically wrong and dehumanizing to both physician and patient.

3. Scientific investigation of the relationship between physician and patient, the forces bringing them together, and the means by which the physician's attitudes and actions affect the patient are necessary.

DELINQUENCY PRONE PERSONALITIES

II. The Sociopathic Personality: Diagnosis

The first article in this series stressed the need to think of delinquency as a symptom occurring in a number of syndromes. The diagnostic groups contributing the largest number of cases displaying antisocial reactions include those where the primary pathology is within the delinquent youngster's personality. These may be sociopathic, schizophrenic, neurologic, low intellect, or severe neurotic syndromes. The most common is the sociopathic personality.

According to Preu[5] priority for describing the syndrome we now call sociopathic goes to Prichard, an English psychiatrist. In 1835, Prichard[6] wrote about a form of behavior characterized by complete inability to make use of education in learning to conform to the social order. These individuals could not profit from experience, no matter how often punished. Though of good intelligence, he called them moral imbeciles, thus emphasizing the deficit of moral capacity. Just as the mentally defective imbecile learns but little in the intellectual areas, these persons could learn but little in the area of impulse control. They were completely selfish, without regard for others, and, indeed, despite their self-centeredness were as well without regard for the consequences to themselves for their acts.

Because of the thinking of the times in the last century and that of later years, the moral imbecile came to be called the constitutional psychopathic inferior, a term introduced by Koch in 1891.[4] That the disorder may be a form of insanity and that it may be constitutional as well, continue to have considerable acceptance, as seen for example in the compelling writings of Harvey Cleckley.[2]

Since 1952, with the revision of the American Psychiatric Association's diagnostic nomenclature, the term used for these persons has been sociopathic personalities. The term sociopathic is descriptive of the focal problem these individuals present: their disturbed social adjustment. It is in relation to other people and particularly with the rules of society that the sociopath has trouble.

Much of the differential diagnosis of sociopathy versus other syndromes is made on the basis of the individual's history. The personality development of the sociopath is almost always marked by frequent bouts with authority. These individuals are mostly boys who, as children, are difficult for their parents to manage. They demand immediate gratification and are sometimes recognized by others as "spoiled." They learn to manipulate their parents, to avoid punishment by deceit and by promises to improve. They are often lavishly rewarded for their ability to avoid responsibility. In school, they underachieve even when of high intellect. They are rebellious and difficult discipline problems. They blame their poor grades on poor teachers, and disciplinary problems are said to be the fault of bullies and/or unfair treatment by the principal. And so it goes on through school into adolescence, where this kind of person begins to show signs of real delinquency. These days that often involves illegal use of automobiles, driving without owner's permission, staying over curfew, stealing ornaments and gadgets, speeding, reckless driving, and even stealing cars. Sometimes this appears not to be more than an exaggerated state of normal adolescent rebellion and striving for independence. Such boys may grow up to be happy, fairly well adjusted, and extroverted adults. Even as adults, however, though they may avoid legal trouble, they usually underachieve their potential, as recent work by Briggs and Wirt[1] has shown. Others, and this *is* a minority, do not make good adjustment as adults and continue in their psychopathic ways until finally they commit felonies which result in long prison terms.

Most of these children are from poor homes deprived both economically and psychologically. The majority have backgrounds of severe neglect, poverty, disease, and dissocial example on the part of parents and siblings. In interview, these youngsters are found to be suspicious of adults, to be bitter about their circumstances, but to be without apparent ability to make sensible plans, to use good judgment or even to use common sense. They

demand a great deal from others but they are unable to share either material things or human emotions. The only emotion they express with conviction is anger. When one hears about the background of such a youngster, one does not wonder at the result. Their histories are filled with rejection, beatings, drunken and promiscuous parents, and direct teaching of criminal attitudes. On the other hand, some come from apparently fine homes, where well-meaning parents of high ethical standards are left frustrated and heartbroken at the failures they have produced.

Psychological tests are widely used in identifying such youngsters. Locally, the most notable of these efforts are in the studies of Hathaway and Monachesi[3] and of Wirt and Briggs.[7] They find that about one-third of all youths adjudicated delinquent are of the personality disposition described. The psychological test used has been the Minnesota Multiphasic Personality Inventory (MMPI). The scales of this test which are elevated in the delinquency prone youngsters are Psychopathic-deviate (Pd), Schizophrenia (Sc), and Hypomania (Ma). Moderate elevations on these scales characterize many adolescents, in fact they are the modal personality pictures seen in youths. In the case of adult offenders, recent research at the Minnesota State Prison by Wirt and Jacobson[8] shows that the majority of the inmates have MMPI profiles and personalities of the sorts just described. In the Wirt and Briggs[7] study, it was found that nearly half of the boys with such a personality configuration who came from deprived home conditions later became delinquent. We are now attempting to devise means for intercepting such boys before the delinquency occurs with the hope that suitable programs of prevention may be devised. The sociopath, whether or not it is possible to effect change in his basic personality structure, may be helped to avoid a criminal career.

There are large numbers of potentially delinquent young people, amounting to about 20 per cent of the total adolescent age group. The research data suggest that, given a weak family and neighborhood environment for a young person with poor frustration tolerance, the probability of his having trouble with the law is substantial. It is imperative, therefore, that prophylactic and remedial procedures be begun as early as possible and that they be aimed at the group most likely to need such treatment programs. At best, treatment for them is a difficult enterprise.

CAN THERE BE SOLO PRACTICE TODAY?

An excellent recent article by Florence R. MacNeill† indicates the current situation in medical care very well—solo practice is no longer "solo." Much as he would like to work alone, the practitioner must work with others in the care of the patient. The quality of care he gives the patient is proportional to the degree to which he can communicate with others.

Unfortunately, independence, which is said to be a prime characteristic of physicians, makes it difficult to get across to some of them the great need for communication and leadership.

Miss MacNeill has used the following quotation from a report of the Massachusetts Medical Society's subcommittee of the National Commission on the Care of the Patient:

"The physician, apparently, has failed more than any other of the human elements involved, to join the patient care lineup as a co-operating factor. Best fitted to lead the team he neither leads nor participates in its joint effort, performing too independently his own functions in regard to patient care. . . . The Committee has astutely put its collective finger on man's greatest failing in the matter of mutual enterprise and human relations—namely, lack of communication."

†*Hennepin County Medical Society Bulletin,* 31:139 (Apr.) 1960.

My field is the area of hospital care, as it is affected by the lack of leadership and communication mentioned above and in Miss MacNeill's article. Before discussing the physician-hospital relationship, however, I should like to point out that the general practitioner in the rural area needs to realize that each of his patients has access to medical information via press, radio, TV, and magazines and therefore is less likely to be satisfied with a few words of explanation than were his parents. The availability of newer drugs makes necessary an explanation of their probable costs, their possible reactions, and the need for *not* keeping any which may not be used, in the expectation of using them for someone else in the family. This latter practice is an old habit but is much more hazardous than it was in former years, when drugs were less potent. The greater selective action also explains why more laboratory and x-ray examinations precede prescription these days.

The patient-physician-hospital relationship should be well launched by the natural leader, the physician. He should know both the patient and the hospital and should be able to explain to the former the whys and wherefores of the latter. He should indicate his part in ordering medications, tests, diets, and so on. It is surprising how many patients do not connect the physician with the fact that breakfast has been "forgotten," yet a word or two from the doctor would save the nurses and the dietary department from blame. Such an incident is always more difficult to erase from memory than it is to prevent from occurring.

A few words to the patient would explain the personnel necessary to help the doctor care for the patient in the hospital and, therefore, the cost of such care. A few more words can outline the benefits purchased by such care, many of which were not available a few years ago.

The doctor knows whether the patient is introspective and sympathetic, or otherwise—a word or two about this to the admitting office may avoid several room transfers, irritated patients, and unhappy personnel. A word of caution about needed isolation and the cost would ease the situation for both patient and cashier.

In summary, the physician should communicate his needs, and those of his patients, to the administrator of the hospital he is using. He should also explain to the patient the part the hospital plays in the patient's care. Only then will a truly satisfactory relationship between patient, physician, and hospital exist.

Mount Sinai Hospital

CLINICAL USE OF GLUCAGON

Glucagon, or the hyperglycemic-glycogenolytic factor (HGF), was first described in 1924. An ephemeral hyperglycemia prior to the expected hypoglycemia was found in the early preparations of insulin. Crystallization of insulin by the method of Abel destroyed this hyperglycemic property, and for several years the initial hyperglycemia was attributed to contaminating substances. When insulin was crystallized by the method of Scott, the initial hyperglycemia was again demonstrated. This stimulated intense study which culminated in the crystallization of the hyperglycemic principle by Staub in 1953. The name glucagon or glucose-producing given to this substance by Murlin in 1924, has been adopted through general use.

According to the best present evidence, the alpha cells of the islets of Langerhans are the major (and possibly only) source of glucagon. Glucagon causes an elevation of the blood sugar through activation of the hepatic enzyme, phosphorylase, which catalyzes the breakdown of glycogen to glucose-1-phosphate. Free glucose is then formed through the action of phosphoglucomutase and glucose-6-phosphatase. A prompt elevation of hepatic vein and peripheral blood sugar results. Glucagon does not stimulate the degradation of muscle glycogen nor does it increase peripheral utilization of glucose.

Clinical studies have shown reliable hyperglycemia following the parenteral injection of glucagon. The intensity and rapidity of the hyperglycemic response is related to the route of parenteral administration. A maximal dose of glucagon has been noted in the normoglycemic individual, beyond which more glucagon fails to elicit further hyperglycemia. In the hypoglycemic individual this may not be true. There is evidence to suggest that the magnitude of rise in blood sugar is closely related to the amount of glucagon that is given. The maximal rise in blood sugar occurs from twenty to forty minutes after injection, again depending upon the route of administration. The duration of hyperglycemia varies from sixty to ninety minutes. Both degree of hyperglycemic response and duration of effect are determined by

TABLE I. BLOOD SUGAR ELEVATION FOLLOWING GLUCAGON
(1 mg. subcutaneously)

Patient	*Initial*	*Blood sugar (mg./100 ml.) 20 min. later*
S.D. #588464	50	97
M.R. #034919	57	127
	285	380
H.H. #504670	35	105
	under 20	65
Y.M. #911188	45	95
H.M. #325295	32	82
J.H. #064409	61	118
	89	103
I.H. #911962	30	70

four factors: (1) the size of the dose of glucagon; (2) the route of administration (i.e., intravenously, intramuscularly, subcutaneously); (3) the intensity of endogenous hypoglycemic activity, and (4) the availability of glycogen in the liver.

The use of glucagon clinically is helpful when acute hypoglycemia is present and the individual cannot take glucose by mouth because of cerebral disorganization or coma. The ease of administration of glucagon surpasses concentrated glucose solutions. One is obliged to give the latter intravenously; glucagon is quite effective when given intramuscularly or subcutaneously. Glucagon is also useful in the patient with chronic severe hyperinsulinism. Its use plus the use of supplementary glucocorticoid and glucose therapy will generally protect the patient from severe hypoglycemia. This latter clinical situation is very rare, while acute hypoglycemia in the diabetic patient under insulin therapy or in the psychiatric patient undergoing insulin shock therapy is relatively common. Glucagon is ineffective when hypoglycemia is due to glycogen storage disease. We have successfully terminated an episode of hypoglycemic coma due to chlorpropamide (Diabinese) with glucagon.

At the beginning of our investigations, we gave crystalline glucagon in doses of 1 milligram (10-20 mcg./kg.) to hospitalized diabetic patients with the signs and symptoms of hypoglycemia. A blood specimen for sugar was taken prior to the injection of glucagon and twenty minutes after glucagon. Table I records a sampling of the cases, showing the response of the blood sugar to glucagon. Because crystalline glucagon lacks indefinite stability, glucagon hydrochloride was developed. This preparation, indefinitely stable in the dry state, is put into solution when needed. Entirely comparable results have been obtained by us with glucagon hydrochloride using identical doses (10-20 mcg./kg.). We have used glucagon intramuscularly or subcutaneously. The intravenous route has been avoided because of its inconvenience. The intramuscular route is very satisfactory for routine hospital use; however, we were obliged to gain experience with the subcutaneous route in order to determine whether the use of glucagon in the home by non-medical people would be feasible. It is inadvisable to permit non-medical people to give injections by the intramuscular route. In general results using the subcutaneous route have been good. We have found clinical recovery to occur 5-15 minutes following an injection. The response is slower when glucagon is given subcutaneously as compared to the intramuscular route. Clinical recovery usually precedes the maximal rise in blood sugar. After clearing of the sensorium, we give the patient a measured amount of carbohydrate (10-20 grams) in order to maintain recovery and avoid a hypoglycemic relapse. The latter may occur with the waning of the effect of glucagon, if vigorous endogenous hypoglycemic activity persists.

Sometimes the desired effect fails to occur. This may mean no hypoglycemia existed. It is very important to obtain a blood specimen prior to therapy with glucagon. If the desired result following glucagon occurs, the specimen can always be discarded. If the desired result fails to occur, one has an initial blood sugar for reference. This procedure has resolved otherwise difficult clinical problems on several occasions. We have seen an occasional patient with proved hypoglycemia who failed to respond to 1 mg. (10-20 mcg./kg.) of glucagon. Recovery was effected with intravenous glucose. These patients have always been comatose. The unresponsiveness may be attributed to poor hepatic stores of glycogen, to sluggish absorption of glucagon, or to the administration of an insufficient amount of glucagon. Rarely irreversible hypoglycemic encephalopathy will be present. Glycogen depletion may occur in the patient with severe liver disease or in the patient with recurring acute hypoglycemia whose glycogen stores have not been replenished. We have been able to document this situation in only one patient. In order to assure an adequate dose of glucagon, we now give 2 mg. (20 to 40 mcg./kg.) to all patients comatose from hypoglycemia; 2 mg. of glucagon hydrochloride can be dissolved in 1 ml. of diluent. We have reserved the use of more than 2 mg. of glucagon at any one time to extraordinary situations. A dose of 2 mg. of glucagon has consistently roused the patient comatose with hypoglycemia.

Glucagon is of great practical value. In a hospital, it can be used by the floor staff much more easily than concentrated glucose solutions when treating the struggling, uncooperative patient, especially the child. The practicing physician will find the treatment of hypoglycemia in the office or home much easier with glucagon for similar reasons. In the home, a family member of the diabetic patient can inject 1 to 2 mg. of glucagon when severe hypoglycemia occurs, using the standard insulin syringe and needle. Many times, this obviates delay in onset of therapy and avoids a midnight ambulance ride to the hospital. The presence in the home of something (glucagon) useful when insulin coma occurs helps allay the anxiety of the patient and family regarding hypoglycemia. We do not advise glucagon for the average mild hypoglycemic episode, unless symptoms linger because of poor absorption of oral glucose due to pylorospasm.

Glucagon is very safe. We have recognized no toxic or allergic side reactions, either local or generalized. The main hazard of glucagon is the omission of close observation of the patient for the desired result. This observation period is mandatory. Glucagon is a valuable addition for the management of hypoglycemia in the hospital, in the physician's office, and in the home.

Fred W. Whitehouse, M.D.

WATER POLLUTION PROBLEMS

Water pollution is a major problem in the control of the sanitary environment and the well-being of mankind throughout the world. This is particularly true in Minnesota where water is so inextricably associated with the development and prosperity of the state. The lakes and rivers provided the first means of transportation and account for the early exploration of the area. They also provided sites for major cities, sources of convenient water supplies and means of transportation. They now must play a major role in meeting the explosive demands of present standards of living and statewide development of urban population, industry and recreation.

There are estimated to be over 5,000 lakes over 40 acres, 16,000 lakes over 10 acres and 24,000 miles of streams. These waters serve over one-third of the total population and more than one-half of the urban population with water for domestic purposes. There are more than 4,000 licensed resorts for people interested in recreation. Many of the major industries, especially those involving food processing, are located here because of the quality of water supplies. These plants frequently require more water with as high a quality as the nearby municipalities. The major portion of the water used by municipalities and industries is not consumed, but must be disposed of after use. The indiscriminate discharge of these waste waters into lakes and streams may be hazardous to public health, to domestic, commercial, industrial or recreational use or to livestock, wild animals, fish and other aquatic life. Its damage may be physical, bacteriological, biological, chemical or radiological. Controlling the discharge of these waste waters and providing treatment so they will not affect the beneficial use of streams is the pollution problem.

The responsibility for pollution rests with municipalities, industries and individuals concerned. State and Federal Control Agencies are partners with them in solving their particular problems.

Minnesota is in a unique position on the top of one of the continental watersheds. Except for one or two minor exceptions, the streams all rise in the state. Little can be done about increasing the rainfall and consequent overall flow of the streams; however, much can be accomplished in keeping the waters clean and of high quality.

Substantial progress is being made in construction of sewage and waste treatment works in the state and there is a growing awareness of the importance of water quality. No sewer systems have been constructed without treatment plants for many years. The cities are growing larger, however, and new industries are being developed and older industries are being expanded. Progress which is made is offset, in some places, by higher water consumption and greater discharge of wastes. The increased use of synthetic chemicals and petrochemicals and the accelerated development of local nuclear energy installations are examples of new sources of wastes which are being encountered today and what may be expected in the future. The success of the program requires the support and attention of everyone interested in conserving the quality and use of this most important resource—water.

George Earl, M.D., Chairman

HEALTH AND MEDICINE BILLS HIGHLIGHT STATE LEGISLATION

Although 1960 was an "off year" for many of the state legislatures throughout the nation, a number of important laws pertaining to health and medicine were enacted by the twenty-two state legislatures that did meet.

Next year all but three legislatures will meet. It is expected that many of the key issues which faced state solons throughout the nation will also be considered by those who do meet next year, including Minnesota.

Members of the Minnesota State Medical Association are encouraged to acquaint themselves with these developments in order that they may be better prepared for what could also become key legislative issues in Minnesota in 1961:

Medical Practice Acts — The West Virginia State Medical Association was faced with a bill which would have made it mandatory for the Medical Licensing Board of West Virginia to issue special permits to graduates of foreign medical schools to practice medicine and surgery for five years, if the graduate had been accepted to practice in a hospital in West Virginia as a house physician under the supervision of the medical staff. The bill did not require that the hospital be accredited and did not define "hospital." The state association vigorously opposed the bill on the grounds that it would lower the standards of medical practice, that it would usurp the power of the Board to pass on the qualifications of those licensed to practice medicine, and that it discriminated against graduates of American schools. The bill was killed.

The Michigan State Medical Society supported a measure which removed a restriction that graduates of foreign medical schools must serve their internships in the state in order to be licensed. The bill became law.

Alaska enacted a medical practice act and also a basic science law.

A bill in Hawaii would have liberalized the licensing requirements for graduates of foreign medical schools. It passed the House but was not enacted.

In Massachusetts, a bill was enacted requiring graduates of foreign medical schools to take the examination of the National Board of Medical Examiners in order to obtain a license to practice medicine. This law was then amended by another measure exempting diplomates of specialty boards recognized by the AMA from the necessity for taking this examination.

Chiropractic—The chiropractors were active in attempting to obtain legal status in states where they are not recognized. A proposal in Louisiana to legalize the practice of chiropractic was defeated by a substantial majority in the state Senate, due to active opposition of the state society.

There was no action in Massachusetts on a bill to establish a licensing board for chiropractors. Similarly, the bills in New York proposing licensure received no action despite very active lobbying by the chiropractors in both houses. There was no chiropractic bill reported in Mississippi, the only other state which presently does not license them.

There were also attempts in New York by the chiropractors to limit the operation of x-ray machines to those holding certificates as x-ray operators, and to exempt chiropractors from jury duty. Both proposals were defeated.

In Alaska, a bill to set up a state board of chiropractic examiners for the purpose of licensing chiropractors received no action, although chiropractic is recognized in that state.

The Rhode Island Medical Society managed to have a bill vetoed by the Governor which would have allowed chiropractors to render "medical care" to public assistance recipients. (Note—an extensive and excellent study on chiropractic in California has just been published by the Stanford Research Institute of South Pasadena, California. The AMA has arranged to have one copy sent to each state medical association. Additional copies are available from the Institute for $5.00 each).

Osteopathy—No action was taken on a bill in South Carolina which would have given osteopaths the right to use and prescribe drugs and to perform surgery. At present, the licenses of osteopaths in South Carolina do not include these privileges.

A Georgia bill to study legislation relative to osteopaths, with the view towards possible revision of the state laws, was vetoed by the Governor.

New York enacted a measure which allows the Board of Medical Examiners to accept the certificate of the National Board of Examiners of Osteopathic Physicians, in lieu of their own state examination, for the purpose of licensure.

A bill in South Carolina, apparently aimed at a particular individual, would have given a license to practice osteopathy to any one licensed to operate a nursing home in the state, and who was licensed to practice the healing arts prior to 1938. This bill was passed, vetoed, and the veto was sustained.

Optometry—A bill was enacted into law in Kentucky which makes it mandatory for all state agencies and political subdivisions to accept and pay for the services of optometrists without discrimination between optometrists and "other persons" authorized by law to render the same professional services. The bill also made it mandatory for the testimony of optometrists to be accepted by state agencies with respect to any matter defined in the state law as constituting the practice of optometry.

Rhode Island enacted a measure allowing the establishment of non-profit service corporations similar to Blue Shield for optometric services.

A bill was vetoed in New York which would have allowed health insurance contract subscribers to have freedom of choice between physicians and optometrists where the contract provides for opthalmic services. A proposal which would make the fitting of contact lenses part of the practice of optometry failed of enactment in Michigan.

Licensure of Paramedical Groups — Numerous bills were introduced proposing the licensure, registration, and control of the many paramedical groups. No attempt will be made to list all of them in this report.

In New York, bills to license and set up boards for radiation technicians and medical technologists failed of enactment.

A measure providing for the examination and registration of persons engaged in the practice of massage therapy received no serious action in Georgia.

The masso-therapists have indicated that they will push for licensure in California in 1961, as will also the x-ray technicians.

A New York bill limiting the administration of physiotherapy by licensed physiotherapists to that prescribed in writing by a physician died in committee.

Anti-Cancer Quackery Legislation—In 1959, California passed the first anti-cancer quackery law. This statute gave the State Department of Public Health the power to investigate and test all drugs, medicines, and devices proposed to be used in the diagnosis or treatment of cancer. The Department has a Cancer Advisory Council to assist in its determinations. If, after investigation and testing, a remedy is found to be useless, the Department is given the power to order its users to cease and desist. If this does not bring an end to the practice, the Department may apply to the Supreme Court of the state for an injunction. The statute also forbids unlicensed persons to diagnose or treat cancer by the use of drugs, surgery, or radiation.

Such laws were also enacted this year in Kentucky and in Nevada. The Kentucky bill required the all-out effort of the state medical association inasmuch as it was opposed by the chiropractors, who attempted to have themselves exempted. In Kentucky, the treatment of cancer is now limited to licensed physicians, osteopaths, and dentists. It is likely that this type of legislation will arouse interest in many of the state legislatures during the coming year.

Health Insurance—The measures introduced in the state legislatures having to do with health insurance are too numerous to mention. The legislatures in New York, Massachusetts, Virginia, and Rhode Island were particularly active in this area.

The bill causing the greatest concern to the state medical association was in New Jersey. This measure would have allowed the Commissioner of Banking and Insurance to disapprove the rates of payment of any medical service corporation or medical service plan. The Commissioner would also have been given the power to obtain any

data or information from a medical service corporation that he needed in order to make such a determination. The bill was vigorously opposed by the state society on the grounds that it would, in effect, allow the government to set physicians' fees without any participation by the doctors in these determinations. No final action was taken by the legislature on this measure although it was favorably reported out of committee to the Assembly.

Bills to set up Commissions to study hospital charges, Blue Cross and Blue Shield rates, et cetera, received no action in Rhode Island and Michigan.

Compulsory Polio Immunization of School Children—Bills in New York and Kentucky requiring the compulsory vaccination of school children against polio received no action. The Kentucky State Medical Association took no position on the bill before its legislature, while the New York bill was opposed by the Medical Society of the State of New York. A similar bill in Michigan was enacted into law.

Exemption from Civil Liability for Emergency Care—California has a statute which exempts persons from liability for civil damages resulting from any mistakes or omissions committed by persons rendering emergency care, in good faith, at the scene of an emergency. Similar "Good Samaritan" laws were proposed in Mississippi, Virginia, and New York. The Virginia bill passed the Senate but not the House. The New York bill was killed in committee, reportedly due to opposition by various non-medical groups. New York expects to have its bill enacted during the 1961 session. The State Medical Society in Maryland also intends to introduce and support this type of bill in the next session of their legislature.

Miscellaneous—The Rhode Island legislature passed a resolution endorsing the Forand bill, and the Teamsters Union in California served notice that they will push for a Forand type bill in that state in 1961.

Physician lien laws failed to pass in New York and Louisiana.

A bill vigorously supported by the Kentucky State Medical Association was enacted setting up a medical care program for public assistance recipients.

Mississippi reduced the statute of limitations on malpractice from six to three years.

Bills in Rhode Island and Georgia, which would have allowed the services of chiropodists to be added to those services covered by medical services corporations, did not become law.

A bill was vetoed in New York which would have allowed podiatrists to administer narcotic drugs.

No action was taken in the South Carolina legislature on a bill which provided for the licensing of naturopaths.

Georgia enacted into law a measure setting up more humane commitment procedures, voluntary commitments, and in general improving the mental health statute in that state.

The Georgia legislature failed to pass a bill which would have clarified the tax status of property owned by professional organizations.

LEGALITY OF NON-THERAPEUTIC STERILIZATION DEFINED

Status of four states (Connecticut, Kansas, Montana, and Utah) proved that it is illegal to sterilize any person for other than eugenical or therapeutic reasons. As to the law on this subject in other states, there seems to be sharp disagreement among the medicolegal experts.

In *Christensen v. Thornby,* 192 Minn. 123, 255 N.W. 620 (1934), a vasectomy was performed upon a man whose wife could not have a child without hazard to her life. This was held not to be contrary to public policy even though the therapeutic necessity was on the part of the wife, not the husband.

A reported decision of a trial court in Lycoming County, Pennsylvania, squarely holds that a contract for a vasectomy, without therapeutic need, is not void because of public policy. In *Shaheen* v. *Knight,* 11 D. & C. 2d 41 (1957), the plaintiff, the father of four children, contracted with the defendant physician for a vasectomy because the plaintiff felt it to be economically necessary to limit the size of his family. Subsequent to the operation, the plaintiff's wife gave birth to another child, whereupon the plaintiff brought suit for breach of contract, seeking damages for the expense of rearing and educating the child. Held: action dismissed; the contract was not void because of public policy, but public policy forbade recovery of the damages sought. The court expressed the opinion that public policy does not recognize the "normal birth of a normal child" as damage.

Public Health

SURVEY OF NURSING ANESTHESIA IN MINNESOTA HOSPITALS

Recruitment, educational programs, consultation services and more complete record-keeping are some of the recognized needs in nursing anesthesia which are evident as a result of the findings of the nursing anesthesia study in Minnesota hospitals. Information on existing conditions was secured by survey of personnel, procedures, facilities and equipment in anesthesia services in general hospitals. The resultant data served as a basis for the present summary and recommendations.

The information reviewed here is taken from an article entitled, "Survey of Nursing Anesthesia: Personnel, Policies and Procedures in Minnesota Hospitals, 1956-57," by Martha J. Lundgaard, CRNA, Helen L. Knudsen, M.D., M.P.H., William C. Harrison, M.D., M.P.H., Bernard A. Wolcyn, Ph.D., and Robert H. White, Ph.D., which appeared in *The Journal of the American Association of Nurse Anesthetists* for June and August, 1960.

An earlier program, supported by the W. K. Kellogg Foundation from 1950-55 indicated the need for more intensive study of paramedical services and the establishment of baseline data which will allow future comparisons. Such will indicate what progress may have been made in providing improved anesthesia services in the State. The reported nursing anesthesia survey was conducted by the Hospital Services Demonstration staff of the Minnesota Department of Health. The project was facilitated by the cooperation of the Anesthesia Advisory Group, consisting of the Minnesota State Medical Association with its Committee on Anesthesiology, the Minnesota Society of Anesthesiologists, the Minnesota Association of Nurse Anesthetists, the Minnesota Hospital Association and the Minnesota Department of Health.

The basic information covering a one-year period was obtained during 1957-58 through personal interview with anesthesia personnel and/or administrators of 182 general hospitals in Minnesota. The questionnaire form consisted of 144 items of which 119 were machine processed to provide data for interpretation. The data was grouped according to five bed-capacity categories (0-20, 21-30, 31-70, 71-130, 131 and over). Forty-five hospitals were included in cities of 10,000 and more population, while 137 hospitals were located in communities of less than 10,000.

In this study, five classifications based on training were used to differentiate anesthesia personnel:

Certified Registered Nurse Anesthetist (CRNA)—a registered nurse certified as a nurse anesthetist by the American Association of Nurse Anesthetists (AANA) on basis of examination since 1945 or experience prior to 1945.

Nurse Anesthetist (non-CRNA)—A registered nurse formally trained in anesthesia in an AANA-approved school, but not certified in anesthesia.

Short-Trained Anesthetist—A registered nurse with anesthesia training in a school not approved by the AANA.

Job-Trained—A registered nurse with only on-the-job training in anesthesia.

Other — Personnel with less than registered nurse training.

The major findings of the survey are summarized as follows:

1. Seventy-five per cent of the 182 hospitals surveyed were in municipalities of less than 10,000 population.

2. Medical anesthesiologists supervised anesthesia services in seventeen per cent of the hospitals.

3. There were 615 anesthesia personnel in the 182 general hospitals in Minnesota in 1956-57. This number does not include the thirty-one resident anesthesiologists and fifty-four student nurse anesthetists in training. Of these 615, there were 447 employed full-time in 125 hospitals. There were 168 part-time anesthesia personnel in 112 hospitals. Hospitals with no full-time people had at least one part-time anesthesia person. Of the 615 anesthesia personnel, fifty-six were medical anesthesiologists, nineteen were physicians with some training in anesthesia, 238 were CRNA's, 278 were RN's who were not certified in anesthesia and twenty-four had no anesthesia training.

4. Approximately one-half of the hospitals (92) in the State did not have the services of either an anesthesiologist or a certified registered nurse anesthetist. The training and background of the individuals providing the anesthesia services in these hospitals ranged from RN's who may have had formal anesthesia training but who have not been certified, to untrained nurse aides.

5. Almost all hospitals employed full-time RN's as nursing personnel in surgery. In addition, slightly over one-third employed practical nurses, and more than two-thirds used nurse aides in the operating rooms.

6. The average maximum monthly salary for CRNA or CRNA eligible was $479.58 in comparison to $346.91 for anesthesia personnel without formal anesthesia training. This is the stated amount paid to anesthesia personnel and does not include pay for call or overtime duty.

7. Full-time anesthesia personnel averaged 6.5 scheduled duty hours per day and 29.2 scheduled hours per week. In addition, the average number of days of first call per week was 4.8. In slightly over one-half of the hospitals, the anesthesia personnel were on call every day.

8. Nearly two-thirds of the hospitals (115) expressed a need for consultant services in nursing anesthesia.

9. RN's untrained in anesthesia techniques administered anesthesia at times in the obstetrical departments of 166 hospitals.

10. One hundred and fifty-six hospitals had gas machines in the operating rooms. Nearly all of the hospitals without machines had fewer than twenty beds. All but two hospitals had suction machines available.

11. Airways of several types and sizes were used in 175 hospitals (97 per cent) while 144 hospitals (80 per cent) had endotracheal equipment available.

12. Intravenous fluids were given routinely in the operating rooms of 165 hospitals (92 per cent) and three-fourths of these used 5 per cent dextrose with distilled water.

13. One hundred and fifteen hospitals had one operating room and sixty-seven had two or more, providing 424 operating rooms in the hospitals studied. A total of 203 delivery rooms was reported.

14. Over four-fifths of the hospitals indicated they had one or more fire or explosion prevention features in the operating rooms. Ungrounded electrical systems, explosion-proof equipment and conductive floors were the most frequently observed.

15. All hospitals gave some type of anesthesia. The most commonly administered anesthetics in surgery were drop ether, local and pentothal sodium. Local block, trilene or trimar were most commonly used in obstetrics. All local, spinal and caudal anesthetics were administered by anesthesiologists or other physicians.

16. Two separate anesthesia records were maintained in nearly all hospitals. Four-fifths of the hospitals (146) used individual anesthesia record form on the patients' charts; the rest recorded anesthesia information on the operative forms or on nurses' bedside notes. In addition, anesthesia information was maintained in various types of record books in all but two hospitals.

17. Nearly three times as many anesthesias were administered to surgical patients as to obstetrical patients. The number of surgical anesthesias was proportionately increased over obstetrical anesthesias as the size of the hospital increased. A total of 212,776 surgical anesthesias was administered in 171 hospitals. More than 145,930 (67 per cent) of these were given in twenty-nine hospitals with 131 beds or more. A total of 78,009 obstetrical anesthesias was administered in 169 hospitals of which 40,977 (53 per cent) were given in twenty-seven hospitals with 131 or more beds.

The following broad recommendations based on the findings of the survey have been developed to suggest programs to achieve better anesthesia services in Minnesota hospitals.

Recommendations

1. An expanded program of recruitment is needed to alleviate the shortage of formally trained nurse anesthetists.

2. Plans should be developed to encourage scholarships for anesthesia training of registered nurses in exchange for a year or more of their services.

3. Educational programs should be established for the presently employed anesthesia personnel in surgery and obstetrics who lack formal anesthesia training. These may take the form of institutes, conferences, refresher courses, consultant visits or other suitable methods.

4. Educational materials and/or programs for hospital boards and administrators should be provided to inform them of the essential features of an adequate anesthesia service.

5. The quality and quantity of anesthesia information being recorded in Minnesota hospitals should be improved and better organized in the interest of improved patient care.

6. Hospital sharing of available anesthetists should be encouraged whereby those who are formally trained in anesthesia can extend their services to nearby hospitals in need of such help.

7. In the construction, remodeling and maintenance of facilities greater consideration should be given to making hospitals safe from explosion and fire. More recovery rooms are needed in the existing larger hospitals.

8. If a recovery room is not planned in the smaller hospital, an emergency cart containing essential post-operative and cardiac-arrest resuscitation equipment should be supplied.

An oral presentation of this material preliminary to the final report was made to the Anesthesia Committee of the Minnesota State Medical Association in May, 1959. Since then a completed report was sent to members of the 1960 House of Delegates of the above body. At the Annual Meeting in Rochester in 1960, the recommendations were acted upon and approved.

Proposed programs based on the recommendations have been developed and were submitted to the Minnesota Patient Care Commission for consideration July 22, 1960. Plans are now being developed to place the program into effect beginning in the fall of 1960.

The Minnesota Patient Care Commission composed of representatives from medicine, hospitals, public health and related groups serves in an advisory capacity for this and similar activities related to patient care services.

State Fair Goers Learn About High Blood Pressure

Free height, weight and blood pressure tests were given to a record total of 7,878 persons who attended the 1960 Minnesota State Fair.

Approximately 10 per cent or a total of 730 persons checked during the ten-day event were advised to consult their personal physicians for further readings. The names of these persons, together with their blood pressure readings, have been referred to the individual's physician. Blood pressure readings were given by members of the Academy of General Practice.

Another popular feature of this year's project was the daily presence of representatives of the Minnesota Dietetic Association to answer dietary questions for State Fair goers. An estimated total of 50,000 pieces of printed health materials, including personal and family health records, calorie charts and *The Healthy Way to Weigh Less* were distributed to the public. Twin City student nurses' groups also assisted in the project.

THE IMPORTANCE OF THE PUBLIC IMAGE VERSUS REALITY

The public image of doctors and the AMA will play a big role in the future course of political and public behavior involving the medical profession, declared Pierre Martineau, Director of Research and Marketing of the *Chicago Tribune,* in the opening session of the American Medical Association's 1960 Public Relations Institute in Chicago. Citing examples of people's reactions to certain products or brand names, Mr. Martineau said:

"Every brand that is well known at all is defined in the public mind partly by what it is but also, very importantly, by sets of psychological associations which may or may not be true. These persist almost like a halo attached to the product. Both of these constitute the brand image and it is to this image that people react in reality. All of our stimuli from the outside are filtered through the images that we have of a particular situation."

It's Word of Mouth that Counts

Images are formed partly by experience but mostly by word of mouth, he said, and once they are formed they become stereotypes that are extremely difficult to alter. We bend actuality to fit the images; we believe what we want to believe.

Mr. Martineau pointed out, however, that images can be modified, but not simply by supplying facts and information. It is imperative, he said, to come to grips with the problem of the doctor and the AMA as they really are and as they are seen by the public, politicians and intellectuals.

Worthiness of Respect and Attention Challenged

Gerald J. Skibbins of Opinion Research Corporation, Princeton, New Jersey, panel moderator, declared that all of our authorities and authority symbols are under major challenge to prove that they are worthy of the respect and attention of the people. A good, strong organization image he said, requires positive, constructive actions that are then well interpreted. He added that bad works also must be explained and remedied.

Here's How People See Doctors

Mr. George Brandenburg, Chicago, Midwest Editor of *Editor & Publisher,* a speaker on the first panel dealing with the subject of "How People See Doctors," reported that relations between physicians and newsmen have been improving steadily in recent years and have never been better than they are today. The real progress, he said, can be credited to doctors "who have learned to be articulate and who have demonstrated to their fellow physicians that you don't have to be a quack to get into print."

However, Mr. Brandenburg added, all is not sweetness and light, and there is no room for complacency. He said there still are too many local instances of professional envy toward colleagues, adherence to the "tradition of silence" and attitudes which create the image of "membership in a secret society." He also urged physicians to take a more active part in civic and community affairs.

Here's How the Doctor Sees Himself

The second speaker, Dr. Russell B. Roth, Erie, Pennsylvania, member of the AMA Council on Medical Service, presenting the image of the truly representative physician as he sees himself, said the "doctor's doctor" has been stripped of the scientific insulation of medical school and has had to face up to countless practical problems and controversies for which his education did not prepare him. Primarily, he is interested in exercising his medical talents, and he would love to be left alone just to heal the sick.

Being paid is secondary thought of the representative physician, Doctor Roth said, and he is proud of his contribution of free services to the needy. He particularly resents the charge of money-mindedness, as he compares his hourly income with that of plumbers and bricklayers. In the gallery of images in the community, he feels that his shines a little more brightly than others.

TV Has Favorable Medicine Image

Herbert A. Carlborg, New York City, Director of Program Practices for CBS Television, reported that experience in the television medium reflects a very favorable image of medicine from the standpoint of both producers and audience. CBS is concerned with presenting the symbol of the doctor in the best possible and most truthful light within the limits of dramatic license, he said, and no material is allowed to glorify negative elements. However, he suggested, television probably should consider doing some programs which, instead of showing a constant pattern of perfection in medicine, would point up some of the controversy that may exist within the profession.

Here's Why People See Doctors As They Do

Members of the second panel, concerned with why people see doctors as they do, were Professor Raymond Mack of the Northwestern University Department of Sociology; Dr. Nicholas Dallis of Scottsdale, Arizona, creator of the "Rex Morgan, M.D." and "Judge Parker" syndicated comic strips, and James E. Bryan of Stamford, Connecticut, consultant in Medical Administration, prepayment and public relations.

Professor Mack expressed the opinion that undoubtedly there are some massive, unfavorable public images of physicians and of the American Medical Association. He suggested that medicine examine its own images of other people, and he questioned the wisdom of placing the socialist label on those in the opposition. We expend too much energy in not liking changes in our social and economic structure, he said, whereas the important thing is how we regulate the so-called "supplementary contracts" involved in those changes.

People Have Double Image of Doctors

Doctor Dallis, who was a practicing psychiatrist for ten years, pointed out that people have two distinct images of the doctor. Their unconscious image of what they want their doctor to be is actually that of Jesus Christ, the Healer. The conscious, realistic image is not one but many, he said, and these vary according to a person's educational, cultural and economic background.

The past twenty-five years of public education about medicine have caused many people to question whether "the doctor's word is law," Doctor Dallis explained. The image also has been affected by the fact that a high proportion of medical school graduates today are married, he said, with the result that young doctors enter practice with more economic responsibilities and greater business ability than those of twenty years ago. The advent of the so-called wonder drugs, making treatment quicker and more impersonal, also has changed the physician-patient relationship, he added.

Do They Desire to Escape Reality?

Mr. Bryan questioned whether "this agonizing concern with our images is not really just another escape device by which we can avoid examining the reality of ourselves." If either our interior or exterior images depart too far from actuality, he declared, "we're likely to be in deep trouble." To treat the image rather than the reality, he added, is to treat the symptom instead of the disease.

A central factor in the tarnished popular image of the modern physician, Mr. Bryan emphasized, is that of "remoteness," the lack of personal involvement between patient and doctor. The average physician has lost some of the art of medicine, he said, and there also is "a profound conflict between the profession's social outlook and the popular ideologies of our day." The profession, he declared, has been far too slow in recognizing the fact that modern medical care is universally demanded as a basic human right.

Minnesota Blue Shield

Minnesota Blue Shield recently announced that individual farmers could apply for its health care plan at group rates, in recognition of agriculture as an industrial group, comparable to Blue Shield groups in other occupational fields.

Dr. Richard R. Cranmer, executive director of Minnesota Blue Shield, said, "Under this program, we recognize the members of Minnesota's farming industry as a group in themselves and are making available to them the same kind of group contract at group rates which business and industry have long received."

He called the action by Minnesota Blue Shield of special importance, because farmers, as a group, tend to have less health care protection than other segments of the population.

Yet, he said, farmers often have greater need for it than some other groups, partly because of the relatively hazardous aspects of their occupation as well as the heavy burden which prolonged hospitalization places on the farm family.

"With the head of the family or other needed adult members absent due to illness, farm operations may come to a standstill, with these losses added to the hospital costs," he said.

Dr. Cranmer added that the new group plan for farmers was a further step in Blue Shield's community-wide approach to the problem of health care protection.

"We regard it as a responsibility of Blue Shield to offer the broadest possible coverage to all groups of the community, and certainly, the farm population is a significant group."

* * *

Minnesota Blue Shield's diagnostic benefits represent a positive step toward the alleviation of one of the most serious problems besetting the health care field. This is the three-fold problem of overcrowded hospitals, rising hospital costs and unnecessary utilization of hospital insurance.

By providing substantial allowances for two of the most expensive items among out-patient services—diagnostic x-ray and laboratory services—Minnesota Blue Shield is encouraging patients to see their doctors sooner than otherwise. In most cases, this permits the physician to detect and control many conditions before hospitalization becomes necessary.

Patients, as all doctors know, have a tendency to delay visiting their doctors because Blue Shield, heretofore, did not cover x-ray and laboratory services when rendered on an out-patient basis. Many patients, who previously waited until they were hospitalized to obtain diagnostic services they could have received while still ambulatory, will now go to their doctors' offices instead.

This has been borne out by experience with prepayment plans in New York City. A study was made of two groups of subscribers there—one group having hospitalization coverage and in-hospital medical coverage, the other having hospitalization coverage, medical care coverage, and in-patient benefits—plus benefits for diagnostic services on an out-patient basis.

Among members of the second group (who had diagnostic benefits), there were 20 per cent fewer hospital admissions than among the group with in-patient medical coverage only. In some areas of New York City, admissions among the second group were as much as 40 per cent lower than from the first group. But the overall average was about 20 per cent fewer admissions among subscribers with diagnostic and x-ray benefits.

The study confirmed, without doubt, the great value of diagnostic coverage in the whole public health picture. Not only does it "help the patient stay well," but, by alleviating hospital overcrowding and unnecessary utilization of hospital insurance, it can, in the long run, contribute to lowering of hospital costs.

HENNEPIN COUNTY MAN SENTENCED FOR VIOLATING BASIC SCIENCE LAW

On July 28, 1960, Robert Paul Selisky, thirty-six, 5260 Hampshire Ave. N., Crystal, Minnesota, was sentenced for violating the basic science law, by the Hon. Harold N. Rogers, Judge of the District Court of Hennepin County, to a term of one year in the Minneapolis Workhouse. However, Judge Rogers stayed the execution of the sentence for one year on condition that the defendant voluntarily enter the Willmar State Hospital for treatment. Selisky must remain in the hospital until discharged, but under the terms of his probation he cannot leave the hospital before the expiration of sixty days from the date of entering the institution. After the defendant is discharged from the hospital, he will be on probation under the supervision of the Hennepin County Probation Office for the remainder of his one-year term. Selisky previously, on July 20, had entered a plea of guilty before Judge Rogers to an information charging him with violating the basic science law by attaching the title of doctor to his name, indicating and with a design to indicate that he was engaged in the practice of healing. Selisky entered the Willmar State Hospital on August 14, 1960.

On July 2, 1960, Officer Walter Bassett, of the Crystal Police Department, arrested Selisky a short time after he inquired at the drug counter in the Medical Center Pharmacy, 5640 West Broadway, Crystal, in order to find out whether a certain prescription had been compounded. Officer Bassett had been informed by an alert pharmacist that a person impersonating a Minneapolis physician had telephoned the pharmacy ordering 100 5-milligram dexedrine tablets for an alleged patient. When Selisky asked at the drug counter for the prescription, the pharmacist called to the officer, which caused Selisky to realize that he was going to be arrested and he then started walking at a rapid pace toward the door. When Officer Bassett reached the door, the defendant had run into an open area and when he disregarded an order to halt, the officer fired several shots into the air. Selisky continued running so the officer placed his gun in his holster and pursued him through waist-high weeds and into a swampy area where it was finally necessary to tackle the defendant in order to arrest him.

The defendant has three prior convictions, two of them being in the Municipal Court of the City of Minneapolis. On September 1, 1954, he was held for police officers at the point of a gun by a Minneapolis man who claimed that the suspect had knocked down his porch railing. Although Selisky was incoherent and acted as though he had been drinking, no odor of alcohol could be detected from his breath and he later admitted to the police that he had been taking seconal and benzedrine. On the following day, the defendant was convicted by the Court of the offense of disorderly conduct, whereupon he was sentenced to sixty days in the Minneapolis Workhouse, the sentence being stayed and the defendant placed on probation for one year. However, on September 18, 1954, Selisky was again arrested, his probation was revoked and he was committed to the workhouse. On August 26, 1956, Selisky was arrested on a charge of violating the City Drug Ordinance in Minneapolis. The defendant was convicted of that offense and Judge Lindsay G. Arthur sentenced him to a one-year term in the workhouse but stayed the execution of the sentence for the same period of time.

Selisky has one prior conviction in Hennepin County for violating the basic science law, the circumstances and the nature of his conduct in that case being very similar to the one for which he was sentenced on July 28, 1960. On November 2, 1959, Hennepin County District Judge John A. Weeks sentenced the defendant to a term of one year in the Minneapolis Workhouse but stayed the execution of the sentence and placed Selisky on probation for one year. Selisky, who was formerly employed by a Minneapolis musical records firm, holds no license to practice any form of healing in the State of Minnesota and has not taken training in medicine.

Use of pHisoHex for washing the skin augments any other therapy for acne — brings better results. Now, pHisoAc Cream, a new acne remedy for topical application, suppresses and masks lesions — dries, peels and degerms the skin. Together, pHisoHex and pHisoAc provide **basic** complementary topical therapy for acne.

pHisoHex, antibacterial detergent with 3 per cent hexachlorophene, removes soil and oil better than soap — provides **continuous** degerming action when used often. pHisoHex is nonalkaline, nonirritating and hypoallergenic.

When pHisoAc Cream is used with pHisoHex washings, it unplugs follicles, helps prevent development of comedones, pustules and scarring. New pHisoAc Cream is flesh-toned, not greasy. It contains colloidal sulfur 6 per cent, resorcinol 1.5 per cent, and hexachlorophene 0.3 per cent in a specially prepared base. pHisoAc is pleasant to use.

A new "self-help" booklet, **Teen-aged? Have acne? Feel lonely?,** gives important **psychologic first aid** for patients with acne and describes the proper use of pHisoHex and pHisoAc. Ask your Winthrop representative for copies.

pHisoAc is available in 1½ oz. tubes and pHisoHex is available in 5 oz. plastic squeeze bottles and in bottles of 16 oz.

In Memoriam

CHARLES H. PIERCE

Dr. Charles H. Pierce, Wadena physician, died September 12, 1960, in Minneapolis. Doctor Pierce was seventy-two years of age at the time of his death.

He was born at Charter Oak, Iowa, in 1888 and received his preliminary education at Park Rapids High School, Park Rapids, Minnesota. He then went on to Hamline University and the Northwestern University School of Medicine, from which he graduated in 1914. He established a practice of medicine in Wadena in 1918. He established the Wadena Clinic in 1927 with Dr. John Grogan, Dr. Harry Frost and Dr. A. F. Schuft (dentist) of Verndale.

Doctor Pierce was a member of the Upper Mississippi Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Survivors include his wife Alfilda, Wadena; two daughters, Mrs. Mary Stabile, Douglaston, New York. and Mrs. Virginia Sheldon, Alexandria, Minnesota; three sons, Dr. Robert Pierce, Renville, Sam Pierce, Wadena, and Attorney Charles Pierce, Pueblo, California; and two brothers, Dr. Willard Pierce, Bismarck, North Dakita, and Walter Pierce, in Holland.

MELVIN VIK

Dr. Melvin Vik, assistant superintendent of the Cambridge State School and Hospital, died September 16, 1960. He was sixty-three years of age at the time of his death.

Doctor Vik was born in Clarkfield, Minnesota, in 1896 and obtained his preliminary education at Clarkfield High School, St. Olaf College in Northfield and the University of Minnesota in Minneapolis. His medical education was obtained at the University of Minnesota Medical School, from which he graduated in 1924.

Doctor Vik practiced medicine from 1924 to 1948 and then served on the staff at the Anoka State Hospital until moving to Cambridge in 1956.

He was medical director of the Physical Medicine and Rehabilitation Service at the Cambridge State Hospital, a member of the East Central Minnesota Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Survivors include his wife, Mercedes; a sister, Mrs. Olivia Hendrickson, Cresco, Iowa; and four brothers, Theodore, St. Anthony, Idaho; Henrick, Sioux Falls, South Dakota, and Olaf and Reuben, both of Clarkfield.

whenever depression complicates the picture

Tofrānil®

brand of imipramine HCl

hastens recovery

Geigy

In many seemingly mild physical disorders an element of depression plays an insidious etiologic or complicating role.

Because of its efficacy as an antidepressant, coupled with its simplicity of usage, Tofrānil is admirably adapted to use in the home or office in these milder "depression-complicated" cases.

It is always wise to recognize that depression may be an underlying factor...that Tofrānil may speed recovery in "hypochondriasis"; in convalescence when recovery is inexplicably prolonged; in chronic illness with dejection; in the menopausal patient whose emotional disturbances resist hormone therapy; and in many other comparable situations in which latent depression may play a part.

Detailed Literature Available on Request.

Tofrānil®, brand of imipramine hydrochloride, tablets of 25 mg. Ampuls for intramuscular administration, 25 mg. in 2 cc. of solution.

Geigy. Ardsley, New York

CONTRIBUTIONS OF $780,000 MADE TO PROJECT HOPE BY DRUG FIRMS

Fifty-two of the nation's leading prescription dru manufacturers have contributed in excess of $780,000 i products and cash to Project HOPE, according to Dr William B. Walsh, president of the People-to-Peopl Health Foundations, sponsor of the project. Over $100, 000 of the companies' contributions were in cash. Pro duct values were computed according to manufacturers wholesale prices.

The donations, coordinated by the Pharmaceutica Manufacturers Association, came from PMA membe companies.

"The support of the member companies of PMA ha earned the unending gratitude of the people of Indonesi and Vietnam," Dr. Walsh said, "And it serves as a example of enlightened generosity to our own fellow citizens. This response has earned the deepest gratitud of all of us connected with Project HOPE."

A part of President Eisenhower's People-to-People pro gram, Project HOPE sent a 15,000-ton hospital ship, th *SS HOPE I,* to Southeast Asia on September 22. Staffe with American doctors, nurses, and medical technicians the floating medical center will bring modern medica knowledge and techniques to the medical and healt professions of newly developing countries throughout th world.

"As a non-government program, Project HOPE coul only succeed with the cooperation and backing of al segments of American society," Dr. Walsh said. "Th response of the American drug industry, many othe industries, businesses, and groups, American Labor, an the American public is proof that our confidence in th conscience of American was warranted."

Dr. Walsh also reported that contributions totalin many thousands of dollars had been raised from non PMA members in the ethical drug industry and fro proprietary drug companies.

Dr. Austin Smith, president of PMA, expressed hi gratitude to member companies for their support an pointed out that "the final success of Project HOPE wil depend on continuing support of all facets of Americar industry and the general public."

"I am informed that HOPE has received more tha $2 million of the $3.5 million needed to operate the shi for its first year," Dr. Smith said.

NEW DIVISION OF OCCUPATIONAL HEALTH

The strengthening of the Public Health Service' nation-wide program to protect the health of America workers through the creation of a new Division of Occu pational Health has been announced by the Surgeo General.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

The new division, which replaces the Occupational Health Program, follows the recommendation of the Study Group on Mission and Organization of the Public Health Service, designed to place greater emphasis on all types of environmental health hazards. It provides for "long-needed increased efforts" in the occupational health field as recommended to the Surgeon General by the Study Group. Dr. Harold J. Magnuson has been named chief of the new division.

To keep pace with a changing technology and multiplying hazards in the work environment, the division will carry out an expanded research program directed at developing better techniques, materials, and equipment for use in the prevention, diagnosis, and treatment of occupational disease. Major research efforts will be intensified in toxicology and in related fields of clinical medicine, engineering, chemistry, and physics. In addition, the physiological and psychological factors in the work environment will come under more penetrating study.

Greater emphasis will also be focused on the training of personnel in occupational medicine and nursing and in industrial hygiene to meet the needs of this rapidly growing field. The Division will work with academic institutions and other groups to help develop the necessary professional resources.

A third area of major expansion is in state aid services, designed to support and assist official agencies in the development and operation of occupational health programs throughout the nation.

The division will also be responsible for stimulating effective community and industrial efforts to supply occupational health services.

Research and technical services, as well as training activities, will be carried out at Cincinnati, Ohio. State aid activities, occupational health nursing consultation, and studies and consultation relating to employee health programs will be centered at the division's administrative headquarters in Washington, D. C.

Use Christmas Seals

KLER-RO

Blood Solvent and Detergent

Removes: BLOOD
TISSUE
SOIL

From: Instruments
Linens
Glassware
Rubber Goods

KLER-RO "Ulmer" effectively removes tissue, plasma, blood, mucus, pyrogens, and many chemical and other types of stains. The use of KLER-RO permits optimum cleansing with as little as ten minutes of soaking and makes unnecessary the harsh scrubbing required with other detergents.

Blood stains and other contamination are readily dissolved in KLER-RO solution without damage to sharp points or edges of surgical instruments. Glass utensils and apparatus emerge from KLER-RO solution sparkling and film-free. KLER-RO is the safest and most dependable cleansing agent for such rubber articles as feeding tubes, catheters, drainage tubes, infusion equipment, and all rubber accessories.

The ULMER PHARMACAL CO.
1400 Harmon Place
Minneapolis 3, Minnesota

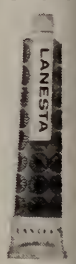
IN CONTRACEPTION...

WHY IS SPEEDIER SPERMICIDAL ACTION IMPORTANT?



Because a swift-acting spermicide best meets the variables of spermatozoan activity.

Lanesta Gel, "...found to immobilize human spermatozoa in one-third to one-eighth the time required by five of the leading contraceptive products currently available . . ."* thus provides the *extra* margin of assurance in conception control. The accelerated action of Lanesta Gel — it kills sperm in minutes instead of hours — may well mean the difference between success and failure.

**Berberian, D. A., and Slighter, R. G.: J.A.M.A.* 168:2257 *(Dec. 27) 1958.*

In Lanesta Gel *7-chloro-4-indanol,* a new, effective, nonirritating, nonallergenic spermicide produces immediate immobilization of spermatozoa in dilution of up to 1:4,000. Spermicidal action is greatly accelerated by the addition of 10% NaCl in ionic form. Ricinoleic acid facilitates the rapid inactivation and immobilization of spermatozoa and sodium lauryl sulfate acts as a dispersing agent and spermicidal detergent.

Lanesta Gel with a diaphragm provides one of the most effective means of conception control. However, whether used with or without a diaphragm, the patient and you, doctor, can be certain that Lanesta Gel provides faster spermicidal action — plus essential diffusion and retention of the spermicidal agents in a position where they can act upon the spermatozoa.

new Lanesta® Gel

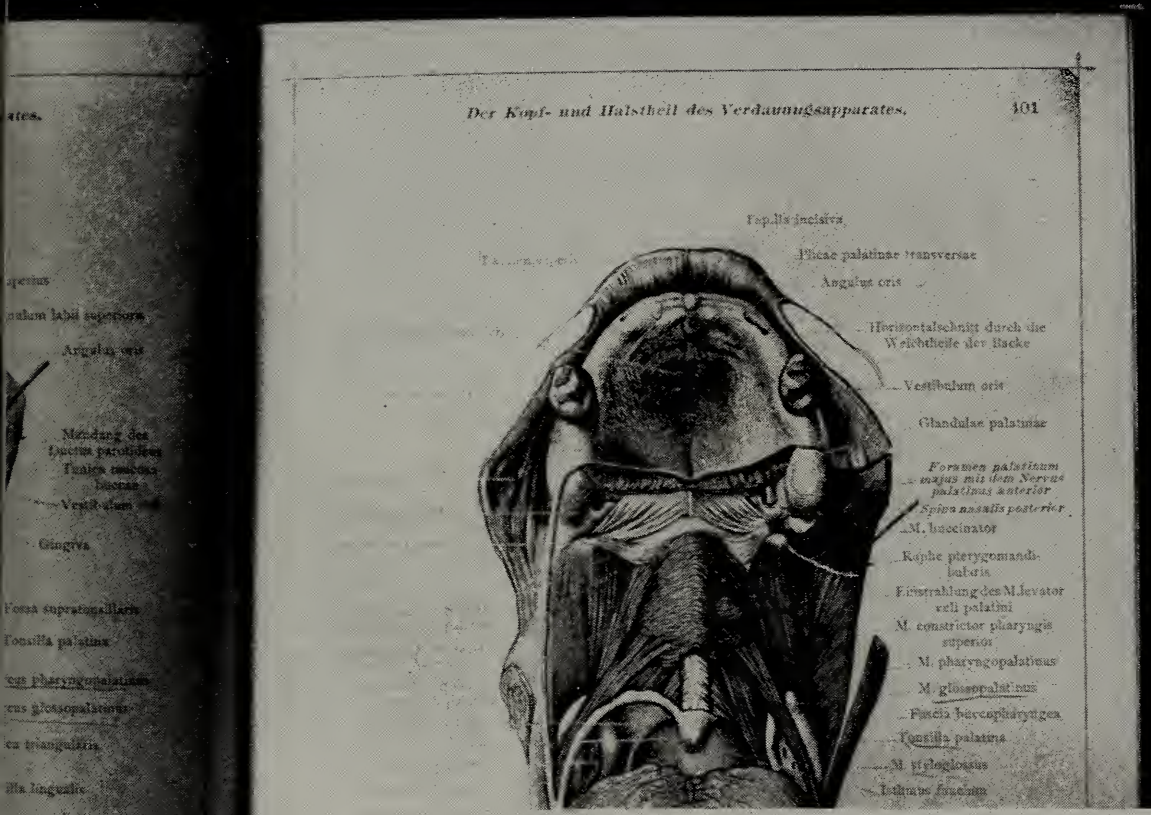
Supplied: Lanesta Exquiset . . . with diaphragm of prescribed size and type; universal introducer; Lanesta Gel, 3 oz. tube, with easy clean applicator, in an attractive purse. Lanesta Gel, 3 oz. tube with applicator; 3 oz. refill tube — available at all pharmacies.

A product of Lanteen® research.

Manufactured by Esta Medical Laboratories, Inc., Alliance, Ohio Distributed by GEORGE A. BREON & Co., New York 18, N. Y.

THE ORIGINAL potassium phenethicillin

SYNCILLIN®



(phenoxyethyl penicillin potassium)

A dosage form to meet the individual requirements of patients of all ages in home, office, clinic, and hospital:

Syncillin Tablets – 250 mg. (400,000 units)... Syncillin Tablets – 125 mg. (200,000 units)
Syncillin for Oral Solution – 60 ml. bottles – when reconstituted, 125 mg. (200,000 units) per 5 ml.
Syncillin Pediatric Drops – 1.5 Gm. bottles. Calibrated dropper delivers 125 mg. (200,000 units)

Complete information on indications, dosage and precautions is included in the circular accompanying each package.

BRISTOL LABORATORIES, SYRACUSE, NEW YORK

Actual case summary from the files of Bristol Laboratories' Medical Department

ACUTE TONSILLITIS

SYNCILLIN®
250 mg. q.i.d. – 5 days

B.G. 9-year-old, white male. First seen Aug. 11, 1959 with acute tonsillitis. Illness of 3 days' duration. Beta hemolytic streptococcus extremely sensitive to SYNCILLIN cultured from the throat. Patient started on SYNCILLIN – 250 mg. q.i.d. After 5 days, the infection appeared cured and the antibiotic was discontinued. No subjective or objective evidence of side reactions.

The Physician's Diary

Dr. Mansur Taufic, a native of Brazil, became an American citizen in naturalization ceremonies in Minneapolis. Doctor Taufic has an established practice as a general surgeon in Austin. He came to the United States on a student visa in 1949 and received a permanent visa in 1957. A graduate of the University of Brazil Medical School, Doctor Taufic studied six and one-half years with **Dr. Owen Wangensteen,** University of Minnesota Medical School surgical division chief.

* * *

New officers of the Southern Minnesota Medical Association are **Dr. Charles G. Sheppard,** Hutchinson, president; **Dr. Grant R. Diessner,** Rochester, first vice president; **Dr. Ed Richardson,** St. Paul, second vice president; and **Dr. John J. Eustermann,** Mankato, secretary-treasurer. **Dr. E. Covell Bayley,** Lake City, is the immediate past president. Guest speaker at the annual dinner was **Dr. Edward M. Litin,** Mayo Clinic. He spoke on "Hypnosis in Medicine—Fact or Fancy."

* * *

A former Thief River Falls physician, **Dr. M. A. Mochal,** has joined the staff of the Worthington Clinic. He is a graduate of the State University of Iowa Medical School and completed three years of residency in internal medicine at the University Hospital and the Veterans' Administration Hospital in Iowa City.

* * *

Dr. Waltman Walters, senior surgeon of the Mayo Clinic, retired October 1, after forty years in the Mayo Clinic. Doctor Walters, a graduate of Rush Medical College of the University of Chicago, is one of the founders of the American Board of Surgery, Inc. Doctor and Mrs. Walters are making an extended study trip to important surgical centers and cancer research hospitals and institutes in the Far and Middle East. They will return to Rochester next June.

* * *

St. Paul physician, **Dr. Gordon R. Kamman,** and fifteen other members of the Academy of Forensic Sciences met with the Japanese Medical Correctional Association in Tokyo. Doctor and Mrs. Kamman were in Asia from July through October.

* * *

Among seven Rochester doctors awarded a total of $24,300 for research are: **Dr. John F. Fairbairn, II,** Consultant in Medicine, Mayo Clinic, for "The Vascular Anatomy and Pathology of the Foot in Arteriosclerosis Obliterans"; **Dr. William H. Weidman,** Section of Pediatrics, Mayo Clinic, for "The Experimental Induction of Congenital Cardiac Defects"; **Dr. Hiram W. Marshall,** Assistant to the Staff in Physiology, Mayo Foundation, for "Application of Fiber Optics to Catheter-Tip Densitometry and Oximetry, and to Cardiovascular Endoscopy"; and **Dr. F. H. Ellis, Jr.,** Head of a Section of Surgery, Mayo Clinic, for "Development of a Synthetic Intracardiac Valve."

* * *

The Fortieth Annual Meeting of the Northern Minnesota Medical Association was held in Crookston recently. The program included scientific sessions at Bethesda Hospital. A banquet was held at the Minakwa Country Club with **Dr. O. J. Behr** of Crookston, president of the Association, presiding. **Dr. Clarence Jacobson** of Chisholm, president of the Minnesota State Medical Association, was one of the speakers. **Dr. C. L. Oppegaard,** Crookston, was general chairman of local committees.

* * *

Dr. Sidney O. Hughes, Winona, has been informed of his election as an associate of the American College of Physicians. He is a graduate of the University of Pennsylvania School of Medicine and served a three-year residency at Presbyterian Hospital in Philadelphia.

hearing improved...

tinnitus
and vertigo
relieved in
circulatory disturbances
of the
inner ear[1]

arlidin®

brand of nylindrin
hydrochloride N.N.D.

effective in twice as many patients

In patients with disturbances of the inner ear— impaired hearing, tinnitus or vertigo — Arlidin produced remission of their chief complaint in over 50% of cases. Rubin and Anderson state "we were very much encouraged, inasmuch as no other vasodilator that we have used has ever achieved more than a 25 per cent response."

"significant hearing improvement"

was obtained in 32 of the 75 patients studied.

rationale:

The clinicians note that impairment in hearing, disturbance in balance, and tinnitus involving t inner ear "may be explained on the basis of labyrinthine artery insufficiency" due to spasm or obstruction of the vessels. Arlidin was found to be "superior to all other vasodilating measures" in increasing blood flow through these vessels and in allaying spasm.

Ulen, Minnesota, will soon have a doctor of its own. ans for the new medical center erected there include npletion the end of this month. **Dr. Gertrude Sax-n,** presently of Moorhead, has accepted the position the new clinic.

* * *

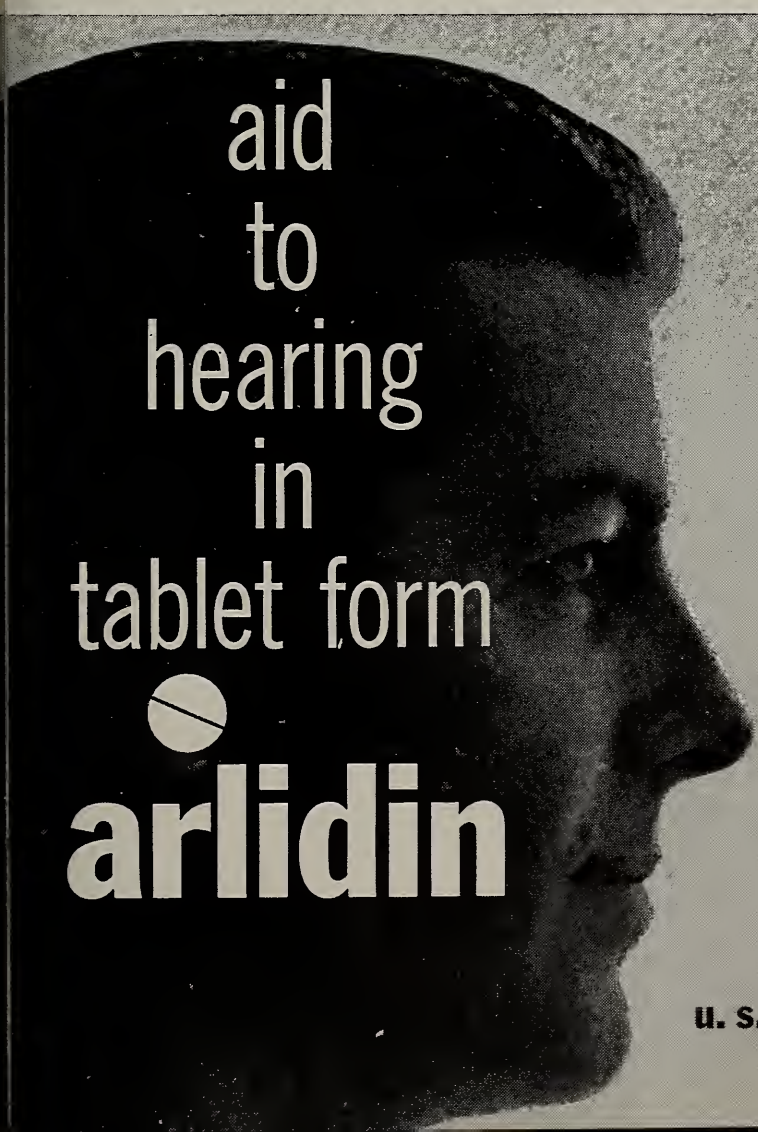
The Mayo Foundation Alumni Association held its rty-sixth annual meeting in Rochester. **Dr. H. J.** ien was general chairman of the event. Officers of the umni Association include **Dr. L. Raymond** Scherer, nneapolis, first vice president.

* * *

Twenty-five years of devoted service to the people of tkin County were recognized as the Community Hos-al Auxiliary members honored **Dr. H. T. Petraborg.** $2500 check to the Hospital Board was presented for dication of the new nursery to Doctor Petraborg.

* * *

Dr. Herman E. Drill, Hopkins, president of the Min-sota Medical Foundation, recently awarded scholar-ps to thirty-one University of Minnesota Medical hool students. This year's awards are the largest group r presented, and bring to 214 the number of schol-hips granted by the Foundation since the program was unched twelve years ago. Total funds for scholarships arded during this period is $109,500.



An emeritus member of the Section of Orthopedic Surgery of the Mayo Clinic, **Dr. Henry W. Meyerding,** attended the World Congress of the International Society for the Welfare of Cripples. After that meeting, Doctor Meyerding served as honorary chairman of the Eighth Congress of the International Society of Orthopedic Surgery and Traumatology. Doctor Meyerding was one of the founders of this society in Paris, France, in 1929, and was president of the Sixth Congress of the group, held in Amsterdam, Holland, in 1948.

* * *

Among the fifteen new members of the Board of Directors of the Sister Elizabeth Kenny Institute are **Dr. Frank H. Krusen,** Rochester, president; **Dr. Miland E. Knapp,** Excelsior; **Dr. Frederic J. Kottke,** Minneapolis; **Dr. E. G. Huenekens,** Minneapolis; **Dr. Paul M. Ellwood, Jr.,** Minneapolis; and **Dr. Owen F. Robbins,** Minneapolis. Mr. Thomas P. Cook, Executive Secretary of the Hennepin County Medical Society, is also a member.

* * *

Dr. Lawrence M. Randall, Mayo Clinic, specialist in obstetrics and gynecology, retired from active practice in the first part of October. Doctor Randall is a graduate of the State University of Iowa and served his internship in the State University of Iowa Hospitals. He served a residency of two years in these same hospitals.

for every phase of cough... comprehensive relief

AMBENYL® EXPECTORANT

AMBENYL EXPECTORANT quickly comforts the coughing patient because it is formulated to relieve all phases of cough due to upper respiratory infections or allergies. Combining Ambodryl®—potent antihistaminic; Benadryl®—the time-tested antihistaminic-antispasmodic; and three well-recognized antitussive agents, AMBENYL EXPECTORANT:

• soothes irritation • quiets the cough reflex • decongests nasal mucosa • facilitates expectoration • decreases bronchial spasm • and tastes good, too.

Each fluidounce of AMBENYL EXPECTORANT ◈ contains:

Ambodryl® hydrochloride (bromodiphenhydramine hydrochloride, Parke-Davis)	24 mg.
Benadryl® hydrochloride (diphenhydramine hydrochloride, Parke-Davis)	56 mg.
Dihydrocodeinone bitartrate	⅙ gr.
Ammonium chloride	8 gr.
Potassium guaiacolsulfonate	8 gr.
Menthol	q.s.
Alcohol	5%

Supplied: Bottles of 16 ounces and 1 gallon.

Dosage: Every three or four hours—adults, 1 to 2 teaspoonfuls; children ½ to 1 teaspoonful. 27160

GENERAL INFORMATION

Authors

Manuscripts should be addressed to Arthur H. Wells, M.D., Editor, 915 East First Street, Duluth 5, Minnesota. Telephone RA 7-6636 or JA 5-2319. Original papers prepared for publication solely in Minnesota Medicine will be considered by the Board of Editors providing they fulfill the following editorial standards. Manuscripts should be typed double spaced on white paper with at least 1-inch margins. The original (not a carbon copy) is requested. The title on the first page should be under six words if possible or divided into two parts. The author should give his highest degree, his institutional position or his relationship to a hospital or medical organization which he may be addressing. Pages should be numbered consecutively and the author's last name should appear at the top of each page.

Bibliographical references should appear on a separate sheet entitled References. They should appear and be numbered consecutively in the order in which they first occur in the text (not alphabetically). Citations in the text require reference numbers if the author's or authors' names are not used or if there is more than one reference to the same author or group of authors. All references to author should appear in the list of References and no references should be included which are not in the text. The style and exact punctuation used in the J.A.M.A. references are requested. Journal references should include: *Author's last name, initial., initial.: title of paper. Abbreviated name of journal, volume number: page, year.* Book references should give author, title, edition number, city, publisher and year.

Illustrations (photographs, tables and graphs) should be submitted separately and not combined in the text. There should be a separate sheet entitled "Illustrations" which contains the various types of illustrations listed separately and numbered in the order in which they appear in the text. All photographs must be in black and white, clear cut, contrasting, and on glossy stock. Instructions for combining photographs are acceptable. Any number of illustrations over 4 are charged to the author. Combinations of photographs up to one-half page (6 x 4⅜ inches) count as 1 illustration.

SPACE MEDICINE

And Astronaut Selection

A. H. SCHWICHTENBERG, M.D.
Albuquerque, New Mexico

THE SUBJECT of space medicine is quite new to the agenda of medical meetings since it has only quite recently become a matter of general interest and vital public concern.

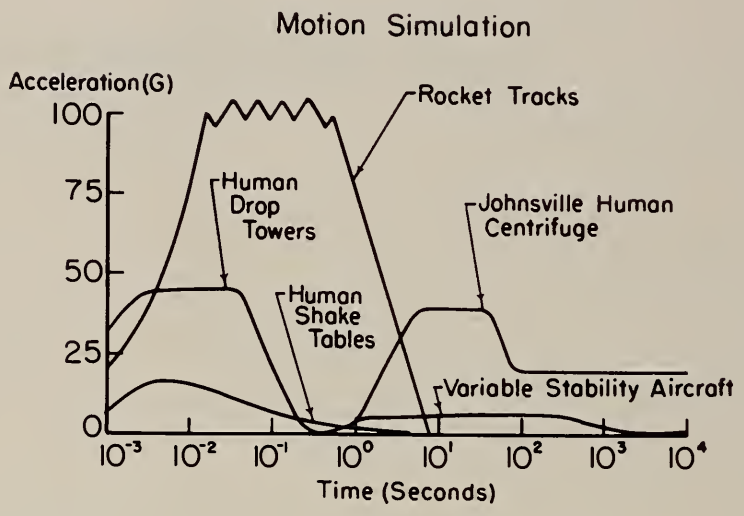
Physicians with their extensive scientific training and background have an excellent appreciation of the enormous scientific and technological progress prerequisite not only to the achievements in space exploration so far, but also those involved in the remarkable weapons systems developments which protect our nation. At the same time it is remarkable to note that physicians have been so slow in adopting many of these advances such as data processing and handling; mathematics and computers; physics and chemistry; engineering and technology and others to medical research and to the everyday practice of medicine. These advances might well have a revolutionary impact.

Dr. Schwichtenberg is Head of the Department of Aerospace Medicine, Lovelace Foundation for Medical Education and Research, Albuquerque, New Mexico.

Much of this slowness is believed due to inadequate communications between scientists, engineers, and physicians. Imaginative physicians with initiative and multidisciplinary backgrounds who can communicate in their own terms with leaders in these rapidly expanding new fields are badly needed. Many of these outstanding individuals are eager to assist the medical profession.

Clinical medicine consists generally of delineating the stresses placed upon the human organism by various disease processes, injuries, toxic conditions, abnormal metabolic processes, psychosomatic, and psychiatric processes. The accuracy of diagnosis and of providing or developing, insofar as possible, appropriate corrective therapy is of primary importance.

Actually, some types of treatment such as surgery, impose serious additional stresses upon the body. Much splendid research effort has gone into extending the frontiers of knowledge in all of these fields and these naturally are the usual subject for discussion at medical meetings.



By contrast, Aviation and more recently, Space Medicine, goes to great lengths to select individuals

essentially free from these kinds of internal stresses familiar to the practicing physician. The stresses that specialists in Aerospace Medicine are concerned with are those imposed upon the human organism by the circumstances connected with flight in the atmosphere around our planet and in the space beyond.

Among the more important of the human stresses that are involved in space flight are acceleration, heat, vibration, radiation, decompression, weightlessness, noise and illumination. In addition there are a number of stressful factors which are more directly concerned with the operation of the space craft itself such as the provision of a proper atmosphere, day-night and rest-work cycles, diet, hygiene, fatigue and psychological factors. These must be studied in order to determine human tolerances and limitations. What has been learned from these studies is of critical importance to design engineers who must develop space vehicles which meet human requirements for an environment in which man can effectively carry out his functions in reasonable safety and comfort.

In addition, the complex tasks confronting an Astronaut in a space vehicle requires a very careful study of how man's talents and capabilities can most effectively be utilized. It is essential to effectively coordinate and integrate man's efforts with the functions and capabilities of the remarkable automatic and semiautomatic sensing and control devices often called "black boxes" which surround him. Many so-called "Human Engineering" studies have been conducted to obtain additional knowledge in this important field. Finally all space craft and component designs and the results of all studies must be verified by checks in the actual environment of space in order to insure efficient functioning and reliable long-term operation.

Detailed references have not been given throughout the paper as is customary since the number would have become unwieldy. The bibliography lists a few carefully selected general references to Aerospace Medicine, each of which contains extensive references that can serve as points of departure for further exploration of subjects of special interest.

U. S. Naval Aviation Medical Acceleration Laboratory
Johnsville, Pennsylvania
from Carl C. Clark, Ph.D.

Fig. 1. Motion Simulator—Devices for Producing Acceleration

I. Acceleration

In projecting manned space vehicles into space environment either in relatively short ballistic flights lasting only a few minutes or for a few ninety-minute orbits around the earth as contemplated in the Mercury project, acceleration is probably the most important of several physical stresses

imposed on man. During the last war, extremely important information was accumulated on the effects of acceleration on man by the use of several human centrifuges at the Mayo Foundation, at Wright Field, the Naval Aeromedical Laboratory, the high-speed sled tests using the tracks at Holloman Air Force Base, and others. Additional information is being collected on the largest human centrifuge in the free world at the Naval Acceleration Laboratory at Johnsville, Pennsylvania. Devices for producing acceleration of various intensities and time durations are shown in Figure 1.

Acceleration is measured in terms of g which is the normal gravitational force acting upon our body and is equal to our mass or weight. If a force equivalent to 2 g should act upon an individual, he would, in respect to the direction of the force, weigh twice as much. The most important measurements in acceleration are the rate of onset in g's per second, the direction of the g forces with respect to the long axis of the body and the time at peak g. Additional factors may also be of prime importance in relation to human tolerance limits to acceleration, such as the combined effects of the other stresses which may be imposed at the same time.

The normal young adult male can tolerate about 5 g for five seconds before blacking out owing to pooling of blood in dependent portions of the body. Three g's may be tolerated for about one hour and Doctor Clark of Johnsville Acceleration Laboratory tolerated 2 g for twenty-four hours. Under this acceleration he noted headaches, anesthesia of a finger, increased water retention, increased white blood count and reduced motivation. Head motions must be kept minimal however, because of the coriolis effect on the semicircular canals which causes disorientation and nausea. Had Clark been in a space vehicle accelerated at this level for twenty-four hours, he would have attained a calculated velocity of 3.8 million miles per hour and would have traveled 45 million miles. Selected music provided an important distraction from generalized discomfort.

Individuals who have been subject for acceleration studies have described the direction of g forces by using the direction in which the eyeballs tend to be displaced. "Eyeballs down" means upward acceleration with relation to the long body axis and is the same as positive acceleration. "Eyeballs up" is the reverse. "Eyeballs in" is forward transverse acceleration and "eyeballs out" is backward transverse acceleration. "Eyeballs right" or "left" would similarly refer to transverse lateral acceleration.

The study of g forces of short duration with rapid onset and high peak values acting in various directions cannot be accomplished on the human centrifuge because of power and structural limitations. For such studies, Colonel John P. Stapp, and associates, at the United States Air Force Acceleration Laboratory at Holloman Air Force Base, has used the high-speed rocket propelled sled,

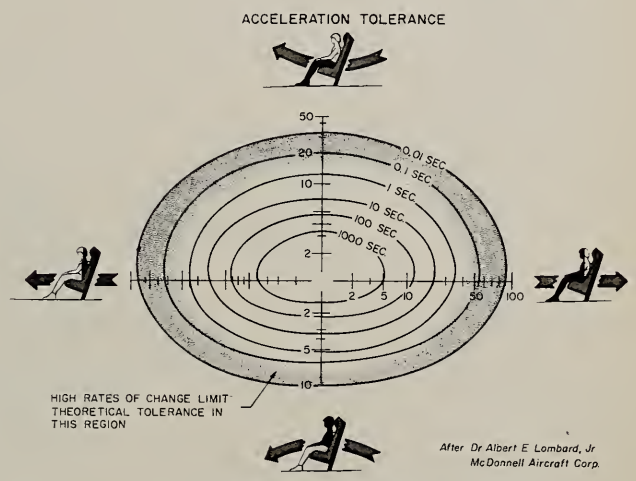


Fig. 2. Acceleration Tolerance

together with an ingenious system of water brakes for the work on tolerance to impact or high g forces, applied with very rapid onset and with very short time durations. Figure 3 shows the limits of human tolerances to such impact type of accelerative forces.

The engineers must design space vehicles so that the man will not be subjected to forces either too closely approaching tolerance limits (Fig. 2) on rocket boost into orbit and re-entry into the atmosphere or those similarly approaching tolerance limits (Fig. 3) on impact with the earth's surface on landing. This is important because of the unknown extent of the adverse effect of other combined stresses on these tolerances. The effect of extended periods of weightlessness on subsequent g tolerance is unknown.

These data have wide application in preventive medicine because they provide physicians and engineers with precise information that can be used

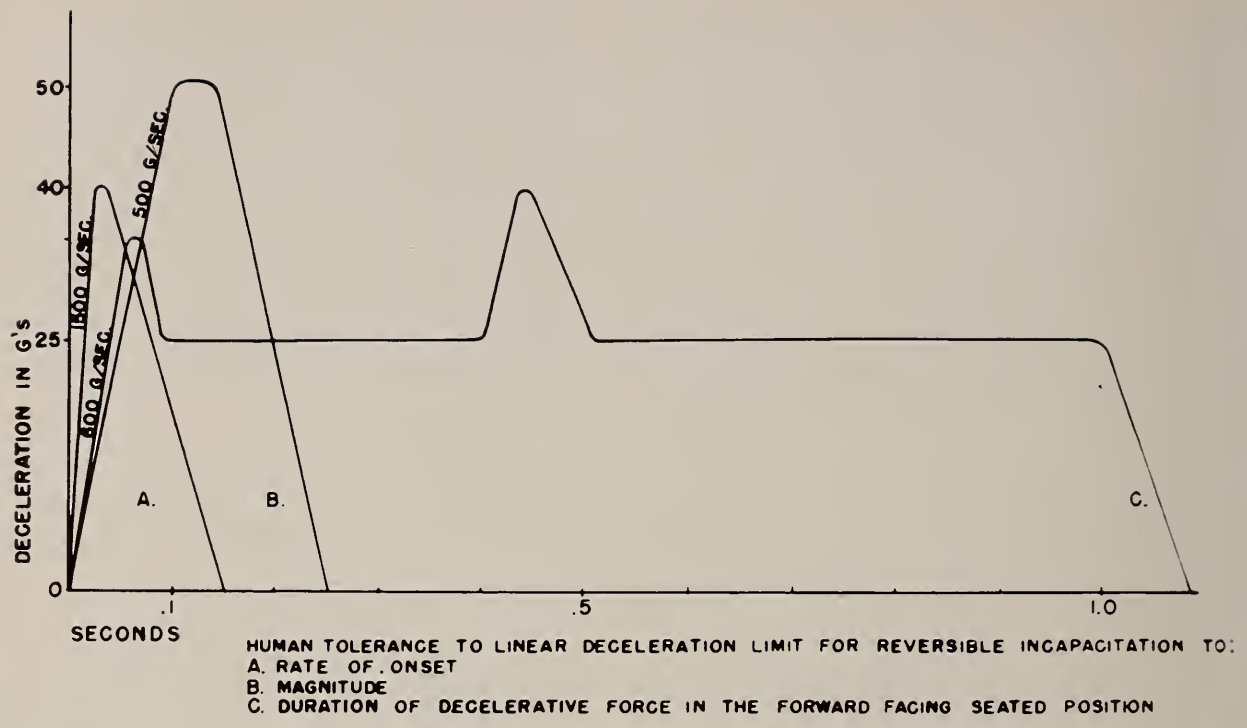

Fig. 3. Tolerance to Deceleration

in automotive and seat belt design. The effective application of this knowledge can save hundreds of lives and prevent many serious injuries now sustained daily by individuals involved in automobile accidents.

II. Heat

So far, the measured heat levels maintained within orbiting vehicles appears to be within tolerable levels. Heating of space vehicles due to aerodynamic heating from air friction has not proved a very serious problem during the boost phase because speeds do not reach high values until the vehicle is largely beyond the earth's atmospheric envelope. The only way heat can be dissipated in space is, of course, by radiation. That side of the capsule facing the sun will become very hot while that facing away will become very cold. Unless equalized by some method or provided for by construction this will set up stresses due to expansion and contraction of the capsule structure which in turn may increase the leak rate of the air within. The problem can be resolved by either slowly rotating the capsule to heat and cool all surfaces evenly, or by a heat exchange mechanism between the hot and cold sides and also by the use of reflective paints or a combination of these. Rotation of space craft to equalize heating and provide some artificial gravity may well have an undesirable side effect in orientation with head movements.

On re-entry to the earth's atmospheric envelope, heating due to air friction or aerodynamic heating becomes an extremely serious problem. This causes most meteors to flash into incandescence and vaporize. The development of successful ways to avoid this for missiles and manned space craft traveling at orbital or near orbital velocities of almost 18,000 miles per hour or escape velocities of over 25,000 miles per hour is difficult. In the Mercury capsule this has been accomplished by the use of an ablation type of heat shield over the base of the capsule.

Precooling of the capsule prior to re-entry to the earth's atmosphere will be accomplished. This stress has been shown to be within human time-temperature tolerances by experiments with volunteers in space suits in heat chambers simulating the calculated times and temperatures of the capsule in its re-entry. These time-temperature calculations have been verified by actual test flights of

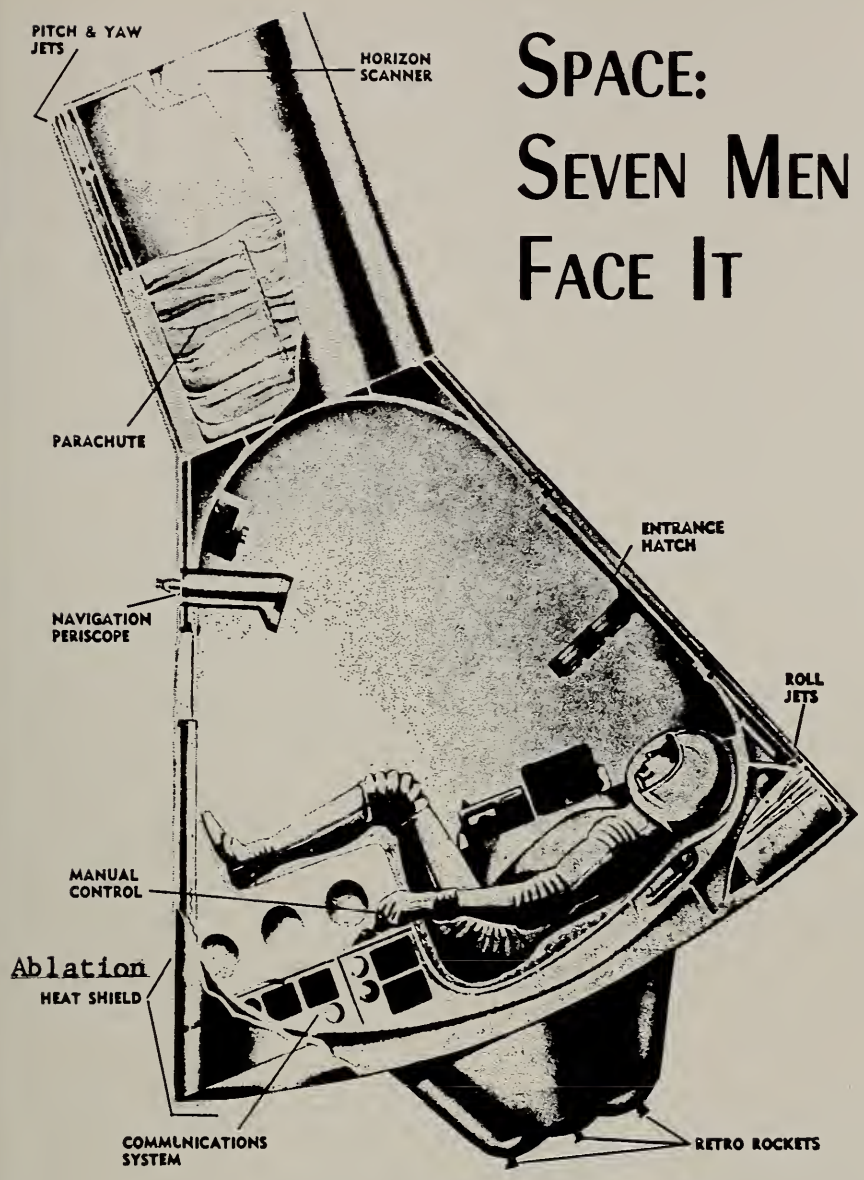

Fig. 4. Mercury Space Capsule

the unmanned and monkey-containing Mercury capsule. Shown in Figure 5 are heat-time tolerances for humans in light, one-piece clothing.

Instead of the ablation shield used in the Mercury capsule, another method of keeping a capsule from burning up is the use of a heat sink composed of materials like beryllium which absorb large amounts of heat. This must be separated from the base of the capsule after re-entry. There is still an additional important method of dissipating the heat of re-entry into the atmosphere. This involves the use of newly developed materials with extremely high heat resistance coupled with the use of stubby winged glider type vehicles (Dyna-Soar), which can skip in and out of the outer atmosphere on its re-entry. This permits alternate heating and cooling by radiation while gradually slowing down for final re-entry into the earth's atmosphere. The wings will also permit some soaring capability when within the atmosphere thus providing choice of landing sites over a radius of many hundreds of miles.

III. Vibration

Vibration has been a matter of concern as a human stress only recently. Most of the work has been done in military aero medical laboratories or under their auspices in other laboratories. It is encountered especially during boost and re-entry phases of rocket flight when it is superimposed on

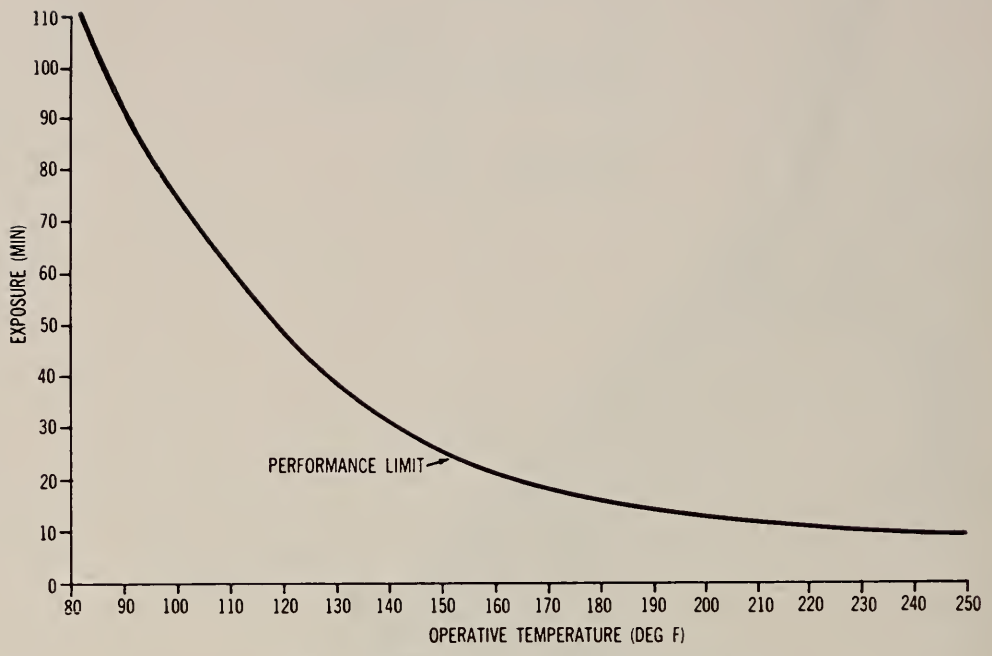

Fig. 5. Heat-Time Tolerances for Humans

For studies of human performance under heat loading, tolerance time is related to operative temperature. (E. T. Carter, *Space/Aeronautics,* July, 1959)

the accelerative forces. Recently studies have been made using the shake-table as a laboratory instrument. Here the subject is firmly fastened to a seat on a table which moves in a sinusoidal manner with an excursion of about one-half inch at various cycles per second (cps). These studies are still in the early stages but indicate that organs and organ systems of the body seem to have natural frequencies so that marked harmonic to- and fro movements are set up as a result of certain vibrational frequencies. These movements place tension upon ligamentous attachments and if continued, depending on the frequency, produce cardiac pain, nausea, and vomiting, also hematuria and bloody stools have been reported. Figure 6 indicates frequencies and related symptoms. The range from 2 or 3 to 30 cycles per second appears to be the most important physiologically though there is another region around 40 cps which also has adverse effects as well. In spaceship design, as well as in industry, structures and operations having these vibrational frequencies should be avoided or the occupant or worker should be shielded from their effect by suitable vibration absorbing or dampening devices.

IV. Meteorites

The environment of space provides a very hard vacuum of 10^{-14} mm. Hg as compared to about 10^{-10} mm. Hg as the best that can be obtained in earth laboratories. In this vacuum one finds meteors and radiation of all kinds traveling in all directions. One advantage of low altitude orbits is that the space vehicle is shielded from almost one-half of these factors by the earth.

Meteors and meteorites are potentially dangerous to space vehicles in proportion to their relative speed, mass and, as a consequence, the energy released on impact with the skin of the space vehicle. The damage ranges from gradual etching of unprotected optical surfaces and the polished

skin of the vehicle from dust particles to small craters from slightly larger masses, to small punctures and finally catastrophic explosions if collisions with sizable meteors occur. Whipple developed the concept of a meteor bumper. It will vaporize most of the smaller meteorites on impact so that hull penetration probability is reduced. The calculated probability of hits on a space craft by a meteorite capable of causing a puncture has been variously estimated from once in a month or so to once per year. On one occasion seventeen impacts were recorded by telemetered sound pickups on a 50 cm. spherical space probe in ten minutes. However, no knowledge is available to determine any damage resulting from these impacts. Much more information from space as well as from the laboratory is required in this area to properly assess the risks and probability of damage as well as how to best provide protection.

From Whipple

Fig. 7. Meteor Bumper by Whipple

V. Hypoxia and Decompression

If the space vehicle is punctured by a meteorite, leaks will occur and if not repaired immediately the passengers will be subject to hypoxia and decompression or aeroembolism. There is limited time available as illustrated by Figure 8, showing time of useful consciousness at various atmospheric pressures. For space vehicles the actual time available will depend upon the rate of pressure loss. The time during which pressure is lost is mathematically determined by the size of the hole, the volume, and air pressure of the space vehicle and the volume of stored gas which can be released per minute in an emergency. The symptoms and dangers of various levels of hypoxia are well-known to physicians and will not be elaborated upon in this paper.

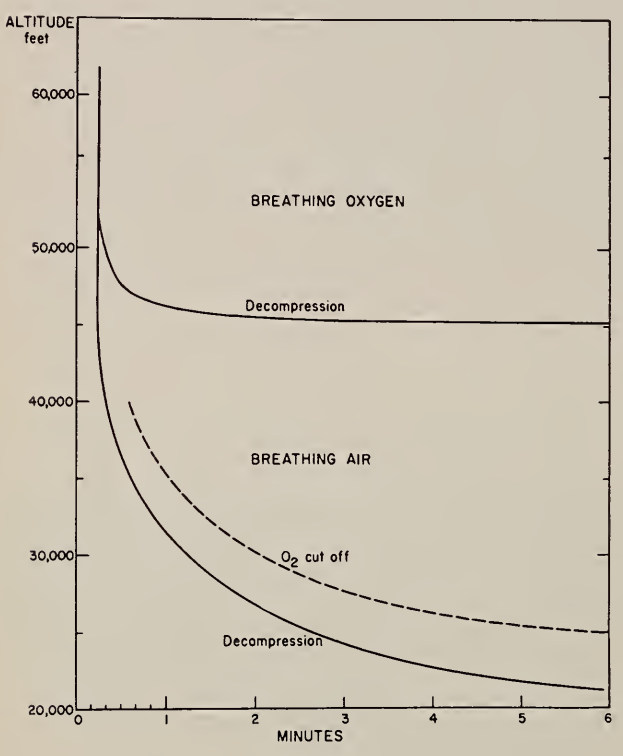

Fig. 8. Time of Useful Consciousness

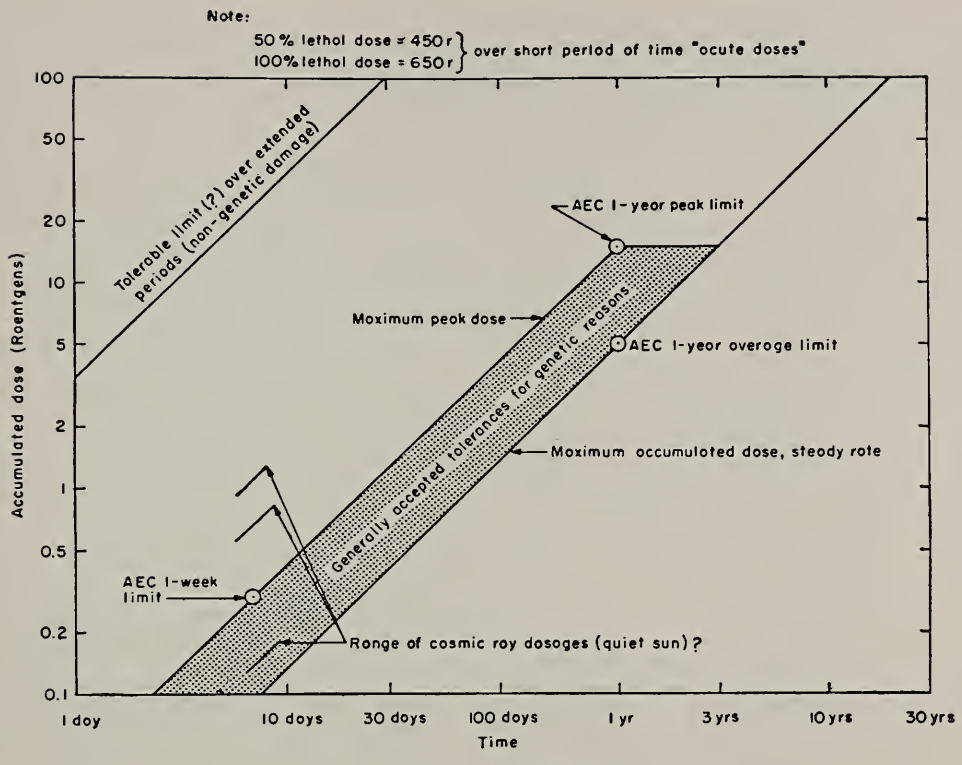
Solid curves: time of useful consciousness at altitude after rapid decompression breathing air (below) and breathing oxygen (above) in pressure cabin. Interrupted curve: time of useful consciousness after separation from oxygen supply in unpressurized cabin.



Somewhat less well-known is another effect of diminished atmospheric pressure related to decompression sickness as seen in divers, caisson workers and more recently in skin divers who remain at considerable depth and pressures for some time then return to the surface too rapidly. Under these conditions, bubbles of carbon dioxide and nitrogen come out of solution in the tissues because the pressure is diminished more rapidly than the excess nitrogen in solution can be eliminated through the lungs. Armstrong proved that just as it was known to be unsafe to reduce underwater pressures by more than one-half at a time with a suitable period for adjustment, so also was it unsafe and symptoms were produced when the atmospheric pressure was reduced by more than one-half as in high altitude aircraft flights without adequate cabin pressurization. He called this aeroembolism.

In either case the symptoms are similar be they in divers, pilots, or occupants of disabled space vehicles and aircraft and depend upon where in the body tissue the bubbles form. Symptoms may be primarily neurological, respiratory, joint pains or skin sensory disturbances and they are often combined. They may be mild and transient, or increasingly severe and occasionally produce permanent disability or death. Since nitrogen is about five times as soluble in oils and fats, individuals who are stout are usually more rapidly and seriously involved than lean individuals. The symptoms can be prevented or delayed by prebreathing 100 per cent oxygen for about two hours during which time most of the nitrogen is removed from the body. This has long been used as a protective measure by military pilots who fly at extreme altitudes.

Until recently, with the advent of commercial jet transports which operate most economically between 30,000 and 40,000 feet, the possibility of exposing other than military pilots and crewmen to decompression did not exist. Improvements in aircraft design and pressurization system reliability following earlier decompression accidents has all but eliminated this possibility in civilian air liners. Until the extent of this problem has been determined by actual experience, occupants of space capsules during the early space flights will wear a full pressure type suit which is automatically inflated, should this become necessary. This will permit the occupant to survive even the vacuum of space for some time.

VI. Radiation

In addition to meteoritic material which has obvious dangers to space vehicles there is a wide

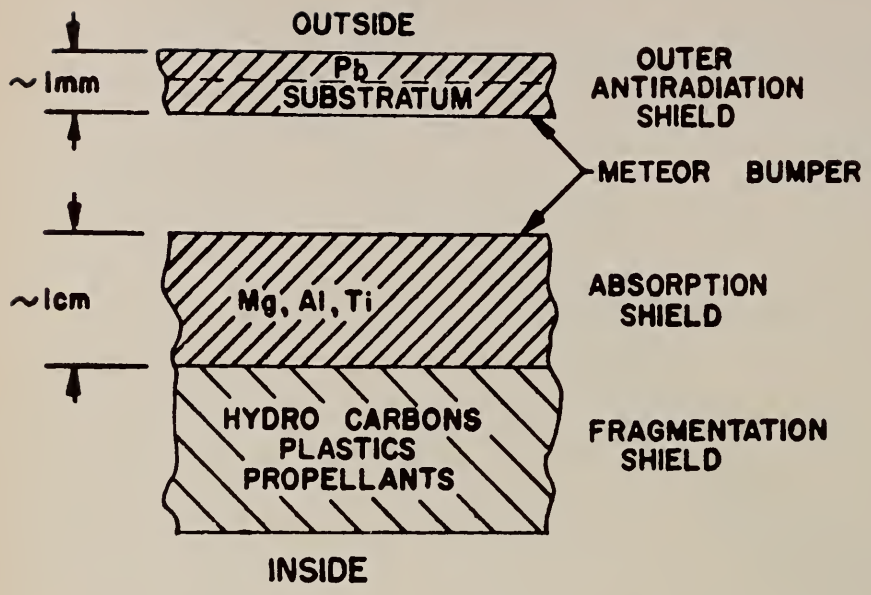
Human tolerances to radiation

Select Congressional Committee, Staff Report
Astronautics and Space Exploration, 85th Congress, 1959
Mr. McCormack, Chairman
Government Printing Office

Fig. 9. Human Tolerances to Radiation

range of radiation, both particulate as well as in the electromagnetic spectrum. Included in these are the cosmic ray particles consisting of protons and heavier atomic nuclei up to and including iron, stripped of their electrons, traveling at near the speed of light and in all directions. They originate in galactic space and from the sun, especially during solar flares. The hull of the space vehicle protects man from some, but by no means all, of this radiation. Most radiation in nearby space comes from the sun and it is now believed that the earth is in the fringe of the solar carona.

There is much more information needed on the particulate and electromagnetic radiation spectrum in space, and additional facts are learned from each satellite and space probe. At present the spectrum of radiation in space is believed to consist of electrons with energy levels ranging up to more than 1 million electron volts (MEV). There are protons with energies ranging up to 500 MEV or even higher perhaps into the billions of electron volts and the heavy nuclei of primary cosmic radiation have energies upwards of 500 MEV as well as beta and x-rays of 0.5 to 5 MEV of bremsstrahlung and nuclear origin. These originate in the hull of the space craft when molecules are struck by high energy particulate radiation and destroyed with the liberation of x-ray and the formation of new materials. Neutrons are also present. The proton radiations, particularly in the inner Van Allen hard radiation belt with energies of about 500 MEV or higher, are similar to those produced by a cyclotron on earth. It requires about 1 cm of lead per MEV to shield against them. Thus 400 MEV protons require about 4 cm. of lead for reasonable shielding. Such a minimum shell of lead 4 meters in diameter will weigh about 5 tons. Much larger booster rockets will be necessary before such additional loads can be projected into orbit. The softer radiation more characteristic of the outer Van Allen belt can be largely shielded by 1 or 2 mm. of lead though re-radiation from the



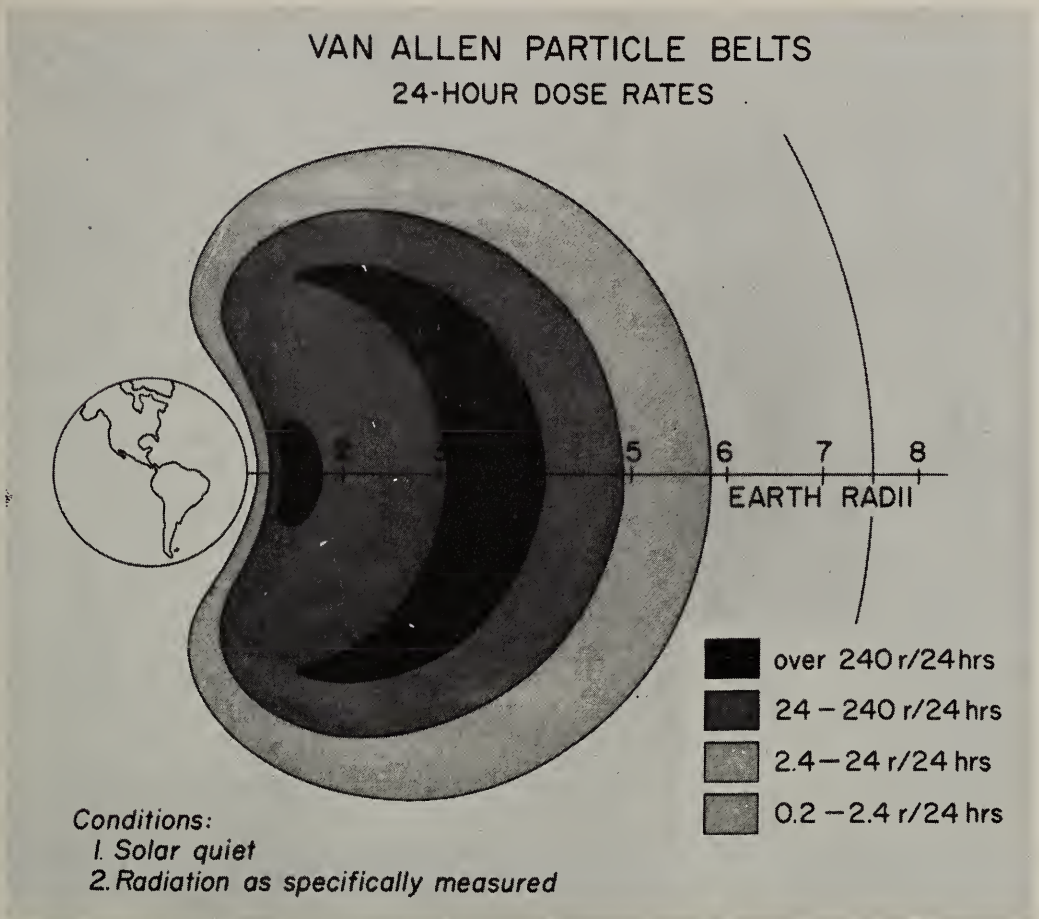


Fig. 10. Radiation Shield Design.

An optimum radiation-shield design based on the presence of a large flux of low energy protons. The outermost layer of lead reduces the radiative processes in these protons by introducing a high Coulomb barrier. This outer skin can be spaced from the inner structural skin using the meteor bumper design suggested by Whipple. The skin of the vehicle itself is made of low atomic number material to reduce the radiation from electrons; also low atomic number materials have a higher stopping power per gram per centimeter than, e.g., lead. The inner layer of hydrogenous material (fuel, propellants, plastic, water, etc.) serves to fragment heavy primaries of the cosmic radiation and thus reduce their biological effectiveness.—S. Fred Singer, Department of Physics, University of Maryland.

hull may present some problems. An optimized radiation shield including the meteor bumper concept is shown as Figure 10.

The medical implications of this level of radiation are obvious to physicians. However, exact determinations of relative biologic effectiveness (RBE) of radiation in space are limited by insufficient detailed knowledge of the spectrum and the inability to reproduce all types of radiation in earth laboratories. In the equatorial plane at about 2000 miles altitude in the inner Van Allen belt the exposure to man, if unshielded, is thought to be on the order of 5 to 10 or more r per hour which would approximate the maximum allowable yearly exposure as now estimated. Until much more powerful rocket boosters are developed to project capsules with shielding into space or possibly until some new approach to shielding is developed, earlier manned space flights must be kept below 400 miles or over about 30,000 miles altitude, well below the inner and outside the outer Van Allen belts, respectively.

Even when space exploration is established, these high-radiation areas will probably be avoided or rapid transit times arranged to reduce total exposure. Nor can one be certain of keeping within allowable limits even in the lower radiation level zones mentioned above because major solar flares may temporarily increase radiation to dangerous levels even in these areas. Without better shielding even in the space outside the Van Allen belts it now appears that radiation exposure may be the limiting factor on the length of trips.

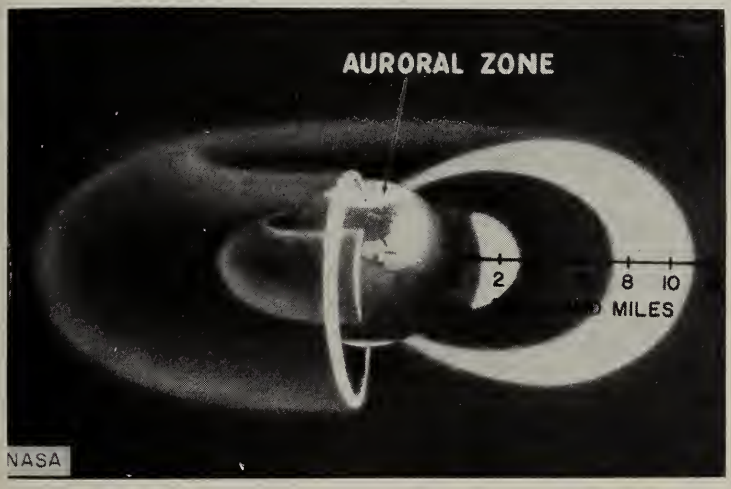

Fig. 11. Van Allen Particle Belts

VII. Weightlessness

No subject has more speculation and less knowledge than the phenomenon of weightlessness. Experiments in aircraft flown in Kepleran trajectories can approximate weightlessness for theoretical maximums of about seventy-five to ninety seconds. Durations of fifteen to about forty-five seconds are more common. Early manned ballistic flights with the Mercury capsule will produce several minutes of weightlessness, but it will not be until orbital flight is achieved that any real information will be available covering several hours' exposure. Based upon the limited experiences gained from animal and monkey shots, it is believed that this will not prove too serious for individuals such as test pilots who have become accustomed to flight and who are trained in weightlessness insofar as this can be done in aircraft. The extent and times to which humans can adapt to extended weightlessness is not yet known.

VIII. Noise

Sound waves of course are not propagated in the vacuum of space though the noise of equipment within the capsule and meteroite hits on the hull will be heard by the man within the atmosphere of the capsule. The medical implications of the noise levels within the capsule are the same as on earth. Noise will doubtless reach very high levels in excess of 120 db., during the boost and re-entry phase of space flight and may adversely affect total tolerance to accelerative stresses when added to the other stresses at these critical periods. Communications may be temporarily impaired for this and other reasons during boost and especially during re-entry.

IX. Illumination

Because of lack of material in the vacuum of space to provide reflectance, the background is very dark and the light is more intensely bright. Thus the instruments may require intense illumination. This becomes marked above approximately 100 km. or 60 miles from the earth where brightness contrasts as high as 1 to 60,000 have been estimated by Campbell. This glare in sunlight and darkness in the shade may well produce eye-strain by continuous efforts of accommodation. Protective lenses will be required when viewing very bright objects in space if retinal damage and disturbances to light adaptation are to be avoided. Again future experience alone can tell how severe this problem will be.

X. Cabin Environment and Atmospheres

It is clear that man cannot function satisfactorily for long periods when enclosed in a full pressure or space suit. While essential for the shorter early flights until the various hazards in space have been encountered and accurately evaluated, a "shirt sleeve" environment should be provided for longer periods. While conjectural at this time it is anticipated that for flights of a month or so, artificial gravity need not be provided. Routine exercises with simple equipment will be required to insure physical conditioning. It has been determined that rotation of a space ship to produce artificial gravity may produce disagreeable side-effects because of the disorientation caused by head movements.

It is expected that a level of compromise in cabin atmosphere will be used to provide 5 to 10 psi pressure with proper oxygen partial pressure to provide near sea-level pulmonary oxygen partial pressure levels. Pure oxygen must thus be furnished if 5 psi is used and inert gas-oxygen mixtures used for the higher pressures. While a simple pressure control is adequate for low-pressure pure oxygen systems, increasingly complex analysis and control systems are required for gas mixtures. For missions of up to about a month's duration, stored supplies of liquid oxygen or the use of super oxides may well prove economical weightwise. Carbon dioxide can be absorbed with lithium hydroxide, odors removed by charcoal filters and various methods can be used for toxic gas removal. Temperature and humidity will be controlled by refrigeration systems. Supercooling to freeze out carbon dioxide and toxic materials as well as remove excess moisture is a possibility. Much has been learned of toxicological problems from naval nuclear submarine experience where prolonged exposure to a given atmosphere has shown that small amounts of substances not previously considered toxic, as used in industry, became so when breathed continuously. For longer flight periods a photosynthetic gas exchanger is desirable using special algeal cultures or hydroponics farms to remove carbon dioxide, liberate oxygen and provide food sources. This still requires a large and costly research and development effort and any system developed must be extremely well tested under space conditions to prove out designs, essential stability of cultures, and long-term reliability under the conditions of space. Liquid oxygen and certain metallic superoxides and electro chemical regenerative systems are possible sources of oxygen.

Algae as food do not provide all the essential amino acids so that additional protein sources must be provided, such as perhaps fish or molluses growing in an algeal solution, as well as perhaps a separate small hydroponics farm supporting chickens, and providing additional food variety. Human and other waste materials must either be dried and stored or incinerated in shorter flights or re-used in the regenerative or closed ecological algae systems for longer periods. Care must be exercised to avoid placing debris in the orbital regions because of subsequent collision hazard. Periodically a very light-weight disposable capsule may be retro-fired in such a way that the capsule

together with all unwanted materials will be incinerated on re-entering the atmosphere.

XI. The Selection of Astronauts

Knowledge and experience gained from Aviation Medicine was the basis for the criteria in the selection of Astronauts. The Special Life Sciences Advisory Committee of the National Aeronautics and Space Administration, representatives of the United States Air Force and Naval Schools of Aviation Medicine, Aeromedical Laboratories, National Science Foundation and civilian specialists joined in developing the selection procedures and medical criteria for Astronauts. It was considered desirable for the first group to consist of specially trained experimental test pilots who met stringent physical and other requirements. They were to be less than forty years of age and weigh less than 180 pounds, with at least 1500 hours of pilot experience, much of which was to have been in modern high-performance jet aircraft and also possess an academic degree in engineering or the basic sciences. They were to be volunteers, very highly motivated, eager and capable of extending their knowledge and training. This was extremely important in light of the NASA concept that in addition to becoming an Astronaut, each one was to be trained to become a specialist in some phase of astronautics, such as propulsion, communications, life support systems, design and construction, navigation, etc. Thus, additional previous training and demonstrated interest and aptitude in these fields were important factors as well as the individual physical and other qualifications in final selection. Later on, volunteer scientists and physicians with special aptitudes, meeting the physical and other qualifications will doubtless be selected for space crews based upon what is learned from the early space flights and the particular mission of future space vehicles. It is believed certain, that in time highly qualified women will also be included in space crews.

There were several phases to the Astronaut selection process, not all of which were connected with medicine. First, records of suitable individuals meeting the criteria noted above were screened, personal interviews arranged to determine interest, and written examinations taken to indicate breadth of readily available knowledge. The physical examinations, physiologic and stress tests preceded a final selection by NASA officials at which time all factors were weighed and the first seven Astronauts selected.

The medical evaluation and selection procedure of special interest to physicians, made use of engineering concepts to some extent as well as long-established aeromedical and clinical medical procedures. In this sense, a most careful medical, family and special aviation history, physical examination, laboratory and x-ray tests were done and were considered generally in the nature of a static test of the body essentially at rest.

An unusually complete physical examination was performed on all candidates including special tests in ophthalmology, otorhinolaryngology, audiology and voice recording, nerve and neuromuscular conduction studies, electroencephalogram, Master's double two-step, tilt table and complete radiological studies using low-exposure techniques as well as a most complete laboratory work-up. A list of tests in addition to routine clinical tests is shown as Figure 12. Part of the laboratory work was to obtain base-line information for future reference.

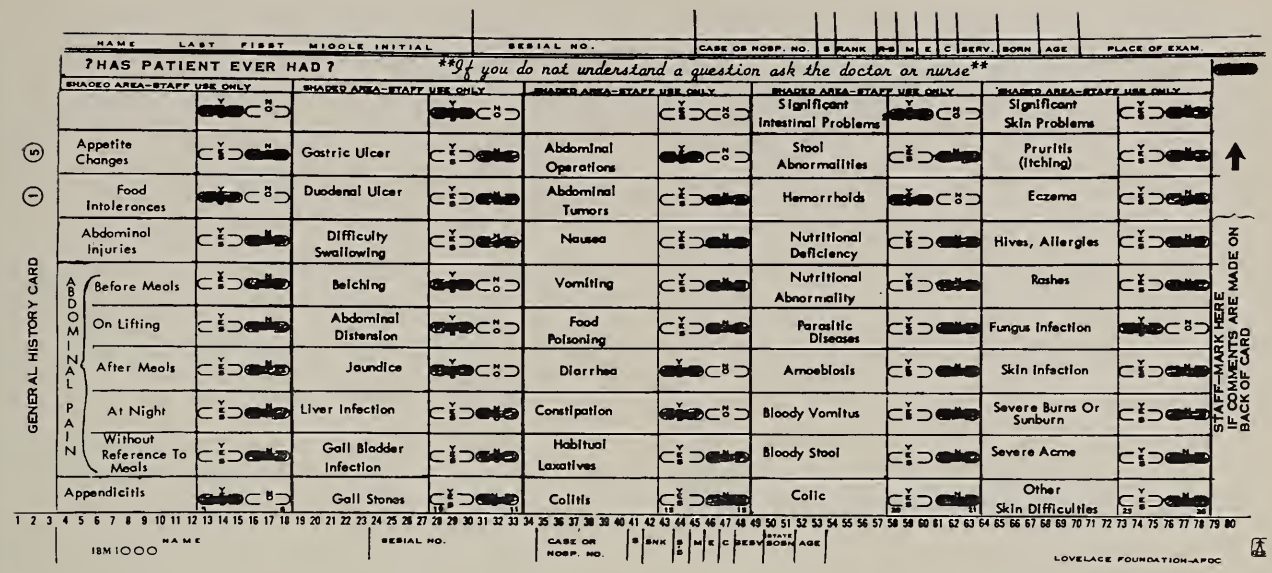
Certain physiological tests of physical competence were added which provided specific information on the maximum physical effort the body was able to exert safely. Here a bicycle ergometer was used. This was considered a dynamic test in engineering and scores achieved were compared to those of normals by age group in terms of oxygen uptake per kilogram of total body weight and per kilogram of lean body mass per minute at maximum effort, oxygen pulse (the number of cc. of oxygen in the cardiac stroke volume at maximum effort), circulating blood volume and hemoglobin.

Total body water, using the tritium dilution method, total body radiation counts, made through the courtesy of the Los Alamos Scientific Laboratories, for total body potassium determinations and body specific gravities were useful in checking the lean-body mass determinations. These tests were done at the Lovelace Foundation and Clinic located in Albuquerque, New Mexico.

The stress tests, conducted at the U. S. Air Force Aero Medical Laboratory at Wright Patterson Air Force Base, carried the concept a step further in that here each individual was subjected to a uniform series of severe physiological stresses and the body responses carefully measured over an extended time period. These are considered roughly analagous to engineering fatigue tests. Blood

PHYSICAL EXAMINATION TESTS PERFORMED

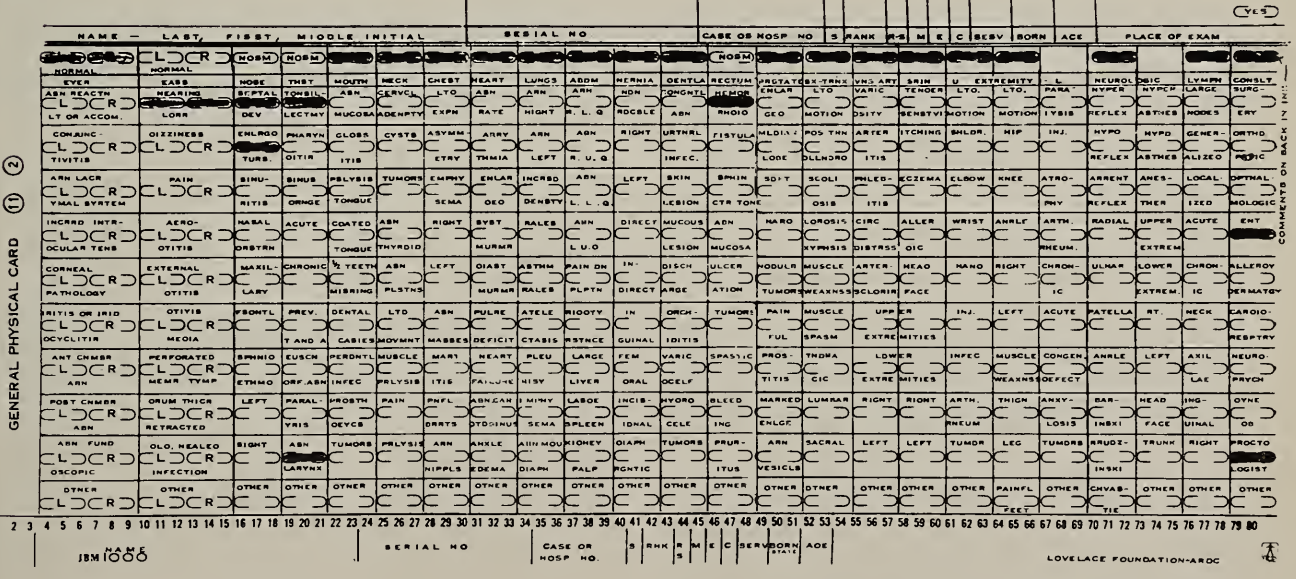
IN ADDITION TO USUAL ROUTINE CHECKS



- Exercise response - blood pressure and pulse rate
- Complete Ophthalmological examination - refraction, slit lamp, dark adaptation, dynamic visual acuity, fundoscopic photography
- Complete ENT examination including caloric test for equilibration function
- Audiology with tape recording of special paragraph reading and perception in 80 db white background noise.
- Dental Examination
- Nerve conduction times and Neuromuscular conduction studies.
- Electroencephalographic study.
- Radiology - Chest, PA inspiration, PA expiration, right lateral colon, sinuses, lumbosacral spine, stomach and oesophagus. *Techniques to minimize ratiation.
- Laboratory - Blood grouping, hematocrit, special hematology smear, gastric analysis, cholesterol, protein electrophoresis, catacholomine, PBI, Serum, electrolyte studies, 24 hour urinary steroid excretion, plus routine blood, blood chemistry and urine test.

Fig. 12. Additional Physical Examination Tests, Astronaut Selection Program

pressure, pulse rate, respiration and electrocardiograms and other measurements as appropriate were made. It now appears as if performance tests while the subject is under stress, so devised that accurate grading is possible, will in the end prove the most meaningful in selecting individuals for space crews once it is determined that they have no medically significant defects. For economy and efficiency these tests may well be combined with training and final crew selection.



The stress tests done at the Aero Medical Laboratories were intended to be meaningful in terms of the stresses to be encountered and included heat tolerance testing for two hours, standard acceleration tolerance, test runs on a centrifuge, altitude tolerance in a partial pressure suit at 63,000 feet simulated in a low-pressure chamber for one hour, isolation tests for a brief period, modified cold pressor tests, vibration tests, performance tests in a high noise field, and additional physical competence tests. Also at the Aero Medical Laboratory, psychiatric and psychological evaluations were made as well as complete anthropological studies.

One of the noteworthy accomplishments in connection with the Astronaut examinations is that all information on all the tests done was recorded on specially designed medical machine record cards of the International Business Machine Corporation (IBM) type. This provided capability of applying modern data-processing and handling techniques in connection with one of the most searching examinations done on any group of individuals. Much correlation work remains to be done in this field.

The IBM type cards can be filled in with minimum instruction, using a special electrographic pencil, by patients, laboratory technicians and physicians. They are automatically processed by machine which punches holes under each mark. One of the History Cards showing the use of the "yes," "no" approach is shown as Figure 13. Should explanatory notes be devised and needed on any card, they may be written in ink on the back of the card and the fact that notes are written on the back is indicated by the mark in the upper right-hand corner.

The physical examination card, shown as Figure 14, is considered a bit too crowded but has the advantage of having most of the general information on one card.

The method of recording numerical data is indicated on one of the laboratory cards and is easy to understand either by the physician or anyone else wishing to obtain information from them. Once these cards have been punched they may be used as inputs to computers and subjected to whatever mathematical study and analysis which may be indicated.

Approximately eighty-five cards were used to record all of the information on each Astronaut candidate. Far fewer cards would be required for routine medical use. The use of a medical work sheet, together with card punch operators for recording medical information also has certain advantages and may be preferred for certain applications.

It is believed that some outgrowth of one of the methods of data recording should be applied to medical practice in order that the many advantages of modern data processing and handling may be realized in medicine.

TRACHEOTOMY

124 B.C. to 1960 A.D.

ROBERT E. PRIEST, M.D.
Minneapolis, Minnesota

IN PREPARING this material, the author has assumed that presidential addresses possess latitude not proper in other types of medical presentations. Much of the material used is taken from work done by me and by my associates over the past fifteen years. The present paper is in the nature of a summing-up of information and thoughts pertaining to tracheotomy. Much of it will be generally familiar to this audience, but it is hoped that it may still prove to be of interest.

In order to conserve time, discussion of several aspects of tracheotomy is being omitted: technique, complications, and instruments including automatic tracheotomes and new types of tubes will not be dealt with.

Tracheotomy was first described just after the beginning of the Christian era. It was credited to Asclepiades who lived in 124 B.C. It probably was first actually performed by Brassavola in 1546. In writing a history of tracheotomy, Goodall found only twenty-eight recoveries prior to 1825. Assuming that some obscure reports were not found, and that some cases were unreported, the number is pitifully small for a period of

Presented as a Presidential Address to the Minnesota Academy of Medicine, St. Paul, May, 1960.

Doctor Priest is Clinical Professor in the Division of Otolaryngology of the University of Minnesota Medical School, Minneapolis.

nearly 2,000 years. As Goodall says, "It is appalling to think of the vast multitude of unhappy infants who must have fallen victims of laryngeal diphtheria from the Hippocratic era to well on in the 19th century."

The increased prevalence of diphtheria in France in the first quarter of the 19th century was responsible for the final and convincing demonstration of the possibilities of tracheotomy by Bretonneau and Trousseau.

Before the 19th century, tracheotomy was contemplated only when suffocation was imminent. An occasional author advocates its early use; de Garengeot in 1720 said, "The operation is very dangerous. Few authors say they have performed it, and fewer still that it proved successful. The reason of it seems to be because they perform it too late, and when the patient is dangerously sick."

The word "cyanche," later spelled "Syanche," and "squinance," appears throughout early writings on tracheotomy. The term indicates severe inflammatory processes about the pharynx. Quinsy and probably inflammations of the floor of the mouth are included.

In 1546, Brassavola, an Italian physician, described opening the trachea of a boy who was nearly dead from an "abcess in the windpipe." This seems to be the first recorded successful case.

In 1620, Habicot reported the case of a fourteen-year-old boy who feared that he was about to be robbed. He wrapped nine gold coins in cloth and tried to swallow the package. It became impacted in the upper esophagus and pressed so hard on the trachea that it partially suffocated the boy. Habicot opened the trachea. Then with a leaden sound, he pushed the parcel into the stomach. In a few days, the boy passed money and cloth per rectum.

Habicot also reported the case of a boy wounded and left for dead. He opened the boy's trachea and removed a laryngeal blood clot. Habicot had two other successful cases, one an officer with a cut throat, and the other a young woman with a gunshot wound of the throat.

In 1714, Detharding recommended that the operation be done on persons apparently drowned. This recommendation was later reiterated by Heister (1739) and de Pouteau (1783) in order that all water might be got out of the lungs through a tube.

Part of the account of the first British tracheotomy, as quoted by Guthrie, is given below. The operation was done and reported by George Martine of St. Andrews in 1730 as follows:

"I was called to a young lad who was all of a sudden taken ill with a violent trouble in his throat in which however I could see nothing wrong. He had great pain and Dyspnoea, with an Impossibility of swallowing. I reckoned it an Angina of one of the worst kinds, and the seat of the disease in the larynx and top of the gullet. Notwithstanding repeated Bloodings, Blistering, Cupping, etc., the Disease continued to be obstinate and the patient so like to suffocate that next day in the afternoon, his Friends, although very averse in the morning, when I first proposed the piercing of the Wind pipe, at length earnestly desired that the Operation might be performed; and the poor Lad bade us try any Experiment to preserve his Life. In a few hours he would have strangled to death most miserably. *Whence you see it was not of an itching Desire of making Experiments, or a wanton Officiousness, that we directly set about the operation.* Which was done with such success, that in less than four Days, his Breathing being perfectly easy, we removed Cannula and left the Glottis to do its own Office.

"Bronchotomy was proposed by Asclepiades 124 B.C., and is described by almost all Writers of Surgery from Paulus of Aegina (625-690 A.D.) and Antyllus (3rd Century A.D.) down to the present time. *But they are at so much pains to defend the Reasonableness of it, without mentioning their own Performance of the Operation, that I myself think it has very seldom been reduced to practice.*"

Here the writer discusses the history of tracheotomy, and gives a description of the operation. Then he proceeds—

"The Cannula should not be made near so short as is ordinarily proposed. The Parts may be so much tumified that it will require a Pipe above an Inch long to penetrate sufficiently into the Aspera Arteria. There would be less Hazard of a stoppage if the Cannula were shorter and wider. I cannot but think it an ingenious proposal of one of our Ministers here to make the pipe double, or one within another; that the Innermost might be safely and easily taken out and cleaned, without any Molestation to the Patient. We found no Inconven-

ience to our Patient's breathing the Air as it passed through the Pipe, without any cleaning or intercepting Medium, though the House was none of the cleanest, being an ordinary Tradesman's here.

"And now I cannot but notice the needless Pain some Writers are in about healing up the Wound by Bandaging, Stitching, etc. For we found it easily to fill up of itself in a very few days.

"Upon the Subject I should not have had so much to say if this elegant Method of rescuing one from imminent Danger, and the most difficult kind of Death, had not been ordinarily described more from Theory than from Practice, and if Surgeons had been half as bold as to assist Nature in such an Extremity as they are officious to disturb her regular and salutory steps."

The technique of tracheotomy evolved slowly. Early operators were afraid to incise cartilage because it was known to heal slowly. They used a transverse incision in skin and trachea.

Tracheotomy tubes were straight and short at first (Fabricius, 1619) and were so illustrated as late as 1795 (Latta's "Surgery"). Casserius (1561-1616) suggested a curved tube with holes in all directions. Sanctorius (1561-1636) advised a straight trochar such as is used in tapping a hydrocele. Martine was certainly the first to mention a double walled tube but he does not say that he used it.

Purmann of Breslau, in a volume entitled "Chirurgia Curiosa" describes "bronchotomy." Purmann is quoted by Guthrie as follows:

"In this manner," he writes, "I opened the Aspera Arteria in Mr. Christian Pfenning Mauven, a linen draper at Munden, in 1672. He was 39 years of age, had a violent Swelling in his Throat and was sometimes ready to be choaked. The Operation being as happily Performed as could be desired, the Patient was perfectly recovered from Death to Life."

A most interesting case report is given below. It is quoted from Guthrie's paper and was originally reported in the *Memoirs of the Royal Academy of Surgeons of France.*

"It appears that, in 1733, a London surgeon named Chovell persuaded a condemned man, a highwayman named Gordon, to allow him, for a substantial fee, to perform tracheotomy upon him the night before his execution. This surgeon had tried the experiment on several dogs and always with success, but his human subject, although still alive when cut down by his friends after the hanging, succumbed very soon. That the case aroused considerable interest is shown by the following anecdote, which Louis appends to his account.

"He tells us that shortly after the execution, three London citizens were stopped on the highway by thieves. One of the three, with great presence of mind, passed himself off as Chovell the surgeon. This name rendered the ruffians so polite that they not only returned his purse, but insisted on accompanying him to London, to protect him from any other attack!"

Until 1930, tracheotomy was reserved for cases of respiratory obstruction at or above the level of the larynx, but Wilson, in 1932, and Davidson, in 1936, suggested tracheotomy for the relief of respiratory insufficiency due to the bulbar form of poliomyelitis, according to Cawthorne.[2] About this time, Cawthorne continues, tracheotomy was suggested as an alternative to repeated bronchoscopy for the removal of secretions in acute laryngotracheobronchitis in children. Galloway, in 1943 and 1947, advocated tracheotomy in various childhood respiratory diseases including bulbar poliomyelitis.[3,4]

In 1947, Priest, Boies and Goltz summarized their experiences with tracheotomy in patients with bulbar poliomyelitis treated at the University of Minnesota Hospitals and the Minneapolis General Hospital during the 1946 epidemic. During 1946, 1830 cases of poliomyelitis were treated in Minneapolis. Almost all occurred during the epidemic period. Approximately 400 were diagnosed as "bulbar" cases. Tracheotomies were performed in seventy-five of these.

Prior to this epidemic, the staff members of the various departments involved had had no experience with tracheotomy in poliomyelitis. Using the few published reports as a guide, tracheotomy was employed cautiously. As the epidemic progressed, the indications became clearer.

As a result of our experience, we said that "we believe that tracheotomy had an important place in the treatment of bulbar poliomyelitis. In certain patients, we think it is a life-saving procedure. There is reluctance on the part of some physicians to accept tracheotomy as a useful adjunct in the treatment of poliomyelitis. Any physician whose experience with bulbar poliomyelitis encompasses only a few cases may question the need for tracheotomy. However, an epidemic

in which several hundred bulbar cases occur produces a considerable number which meet the criteria for tracheotomy outlined in this paper."

In a thorough search of the literature from 1900 through 1946, we found no report of a large group of poliomyelitis patients subjected to tracheotomy. No further reports were found in a bibliography covering the literature from 1789 to 1944.

As might have been anticipated, the reactions of the medical world were varied. Some authors took issue with the Minnesota group, saying its treatment of certain cases had been too radical and might even have prejudiced the chances for recovery of some patients. Other commentators agreed with the Minnesota group.

Five years after the 1947 publication, Priest, Boies, Goltz, Younger and Koller[5] undertook to review the world's literature to assess the opinions expressed concerning tracheotomy in bulbar poliomyelitis. About twenty-six papers on tracheotomy on bulbar poliomyelitis has been published since 1947. These represented all shades of medical opinion. Some criticism was truly bitter, but it is of interest that the bitterest critics had not used the method. The preponderance of opinion favored the method.

A large poliomyelitis epidemic in Denmark finally convinced the medical world that tracheotomy could be a life-saving measure in respiratory obstruction arising from any part of the respiratory tract.[2]

The tendency for more and more operations to be done for respiratory emergencies other than the traditional one of laryngeal obstruction is well illustrated in Table I, made up from figures quoted by Nelson (1958).[2]

TABLE I

	For laryngeal obstruction	For other causes of respiratory insufficiency
1940	98%	2%
1954	53%	47%
1958	48%	52%

Thus, within the past twenty years, the indications for tracheostomy have extended beyond the classical and obvious one of relieving obstruction to the entry of air into the tracheobronchial tree, and now more than half the operations are performed to prevent or to overcome respiratory insufficiency from other causes.

Quoting Cawthorne further:

"The extended use of intratracheal anesthesia and in particular the use of closed circuit machines made the anaesthetists appreciate the potential danger of dead space air, particularly when the breathing was shallow. From this has come the realization that, in the shallow respiration of profound unconsciousness, the reduction of the dead space air from 150 c.c to 50 c.c. by means of tracheostomy may in itself be life saving.

"Finally, the introduction by anesthetists of the cuffed intratracheal tube, which effectively isolates the lower respiratory tract from the digestive tract and at the same time allows for positive pressure respiration, has solved the problem of 'inhalation pneumonia,' and has rendered the iron lung almost obsolete; and there can be few, if any, of those who have had to cope with patients in iron lungs who will regret this.

"The stimulus for this last step came from Denmark when, in 1952, they were struck by a serious epidemic of poliomyelitis with many cases of respiratory paralysis and not enough iron lungs to go around. They had to improvise, and by means of tracheostomy with cuffed tubes and by using teams of medical students to operate manually the positive pressure apparatus, many lives were saved. This led to the development of the mechanical positive pressure breathing machine."

An outstanding contributor to this phase of the extended use of tracheotomy is a member of this society, Dr. Frederick Van Bergen.[7]

Recently, trauma to the head, face, neck and chest has provided many indications for tracheotomy. In times past, most tracheotomies were done to relieve obstruction of the airway caused by inflammatory conditions or neoplasms. Acute injuries of rather severe degree are becoming more common in our modern civilization with its rapid transportation.[8]

Tracheotomy is a useful procedure in head injuries with cerebral concussion, even though the face and neck are not injured. In the unconscious patient, the jaw relaxes, the tongue falls back into the throat, and evacuation of secretion from the pharynx by voluntary means under control of the patient ceases. Pooling of secretion in the pharynx may occur, and aspiration of this secretion may follow. Aspiration of vomitus is not uncommon. The use of feeding tubes produces irritation of the pharynx and causes more secretion to be formed in the pharynx. Cough reflex is at a minimum of efficiency. The use of tracheotomy to permit frequent and adequate cleansing of the lower respiratory tree has grown

steadily in recent years. Similar indications exist in barbiturate and other poisonings.

Jaw fractures, injuries to the front of the neck with edema of the pharynx, and fracture and edema of the larynx make it necessary to provide an airway by opening the trachea below the point of injury; inability of the patient to clear his own airway may occur in these conditions, as well as in cerebral concussion or poisoning.

Tracheotomy in burns may be necessary because of aspiration of hot gases which cause edema of the larynx. In World War II, it was found that aviators who were apparently in good condition when rescued from burning aircraft sometimes died unless "prophylactic" tracheotomy was performed; secondary swelling of the laryngeal interior occurred, and the patient died of asphyxia even though all other potential causes for death were under control.

During the past few years, the use of tracheotomy in the treatment of chest injuries has become more and more widespread. The purpose of tracheotomy in chest injury is twofold. Cleansing the lower respiratory tree by suction through the tracheotomy is probably the most important reason for doing tracheotomy in chest injuries. A second indication occurs in the so-called "flail chest." Here a large segment of the chest wall "floats," and there is paradoxical motion on respiration. When the patient breathes in, the flail segment of the chest goes in instead of out, because it is no longer anchored to the rest of the chest wall.

It has been shown by several authors that patients with flail chests do better with tracheotomies, because the total volume of air moved during the respiratory act is reduced. Resistance of air coming in through the tracheotomy is less than through the nose and pharynx. Experimental work measuring pressures in the pleural spaces before and after tracheotomy in human beings and in dogs has shown a definite advantage in the case of tracheotomy.

Positive pressure can be applied during the inspiratory phase of respiration to provide stabilization, or at least partial stablization, of the flail segment of the chest. This reduces pain and also increases respiratory efficiency.

Tracheotomy for relief of secretional obstruction in unconscious patients is not confined to head injury cases. It is useful in central nervous system vascular accidents, poisonings, botulism,[9] and drug overdosage, when the patient cannot clear his own airway of secretion. Of course, tracheotomy does nothing to overcome the primary disease *per se*. But it removes one deleterious factor from the patient's course, and hence allows him to be able better to overcome the primary disease.

Summary

Tracheotomy was described in 124 B.C., but was first performed in 1546 A.D. Up to 1825 A.D., only twenty-eight recoveries were found recorded in medical literature. Assuming that some obscure reports were not found, and that some cases were unreported, the number is pitifully small for 2,000 years. In the 19th century, diphtheria in France demonstrated the advantages inherent in tracheotomy.

Until about 1930, tracheotomy was used only when suffocation from airway obstruction above or in the larynx existed. Then its value in overcoming secretional obstruction was recognized. Since then, its usefulness in bulbar poliomyelitis, head injury, burns, drug and microbial poisonings, chest injury, as well as in laryngeal and pharyngeal obstruction, have become apparent. The operation described by Fabricius of Aquapendente (1537-1619) as "the scandal of surgery" has now assumed a respected place in man's therapeutic arsenal.

Fig. 1. *(a)* When seen initially, the patient had soft, nodular, dome-shaped lesions that had begun as papulovesicles a week before. *(b)* Four weeks later, the lesions had resolved almost completely with local antibiotic therapy and wet dressings.

Orf:

A viral disease of sheep bearing the fascinating name of "orf" is a hazard of sheep farmers. Although the disease is severe in sheep and goats, it practically always is mild in humans, being confined to the skin. Sheep farmers presenting dome-shaped, soft, moist, deep-red cutaneous nodules may have orf. If you like to collect new diseases, why don't you scan this little article?

ORF (ecthyma contagiosum) is a disabling or even fatal disease of sheep and goats that often results in losses among lambs and kids amounting to hundreds of thousands of dollars annually.[1] Humans are also susceptible to the virus and, in many parts of the world, this infection is a common occupational disease among sheep farmers.[2] In Minnesota, its rarity may be less apparent than is actually the case, inasmuch as the disease may be unrecognized.

From the Section of Dermatology, Mayo Clinic and Mayo Foundation.

Read at the meeting of the Southern Minnesota Medical Association, Mankato, Minnesota, September 12, 1960.

Dr. Farmer is a Fellow in Dermatology, Mayo Foundation.

The Mayo Foundation, Rochester, Minnesota, is a part of the Graduate School of the University of Minnesota.

Report of Case

A twenty-seven-year-old sheep farmer from southwestern Minnesota recently came to the Mayo Clinic because of isolated "sores" over the right arm, left shoulder and face. He was primarily concerned about the cosmetic disfigurement produced by the lesions. He felt well and was essentially asymptomatic except for slight tenderness localized to each of the involved zones. All the lesions had begun at about the same time, which was one week before he came to the clinic. He first noted papulovesicles that later became confluent to form moist, dome-shaped lesions with some superficial crusting.

JOHN L. FARMER, JR., M.D.
HAROLD O. PERRY, M.D.
Rochester, Minnesota

Fig. 2. Biopsy from a lesion on the right arm shows the histologic picture of an acute viral infection. The epidermis is acanthotic, with intra-epidermal vesicles resulting from reticular degeneration of epidermal cells. A mild inflammatory infiltrate composed mostly of lymphocytes is present in the dermis.

An Occupational Disease in Minnesota

He had raised sheep for several years, at present having a total of 225 sheep, 105 of which were lambs; sixty of the lambs had orf, or sore-mouth disease. The local veterinarian suggested that he treat the infected animals with a disinfectant spray; while carrying out this program, the patient sustained multiple scratches and abrasions about the hands and forearms. Within five to seven days, he noted small isolated zones of papulovesicles on the right forearm, left shoulder and face at the sites of the trauma.

Examination revealed a young white man in apparent good health. He was afebrile and did not have any lymphadenopathy. The positive physical findings were limited to the skin and consisted of six nodular lesions measuring from 0.5 to 1.0 cm. in diameter. Four of these lesions were on the face, one was on the right arm and one was on the left shoulder. All the nodules were similar in appearance, being dome-shaped, soft, moist and deep red, with slight superficial crusting that partially obscured a clean, moist, granular surface (Fig. *1a*). A slight inflammatory halo surrounded each lesion.

Therapy consisted of the local application of an ointment (neosporin) containing polymyxin B sulfate, neomycin sulfate, zinc bacitracin and petrolatum. This was applied to each lesion several times daily, alternating with wet dressings moistened with tap water, which were applied at intervals to remove the accumulated crusts and exudate.

At the end of two weeks, most of the lesions had begun to regress; however, one new lesion had developed in the left supra-orbital region. At the end of four weeks, the lesions showed further regression (Fig. *1b*). Three months after the initial visit, all the lesions had healed, with little or no scarring.

Comment

The term "orf" is derived from the old Anglo-Saxon word for cattle; in its modern usage, however, it refers to a viral disease occurring primarily among sheep and goats.[3] The disease is world wide in distribution. It was first reported among sheep in the United States in 1928 and is now known to be widely distributed throughout the sheep-raising areas of this country.[1,4]

The virus that causes orf belongs to the genus Borreliota, or the pox group of viruses. It is comparatively large, probably being nearly the size of the vaccinia virus. Elementary bodies have been observed with the light microscope by staining for the Paschen bodies of variola.[5]

Orf should not be confused with sheep pox, as the two are separate and distinct diseases. Orf is a benign viral disease of the dermotropic type, and it does not present systemic manifestations when the condition is uncomplicated. Sheep pox, somewhat analogous to smallpox in man, is a systemic viral disease in which the cutaneous involvement is only one facet of the infectious process.

Animals other than sheep and goats at times may acquire the infection. The chamois, a goat-like antelope found in the mountains of Europe, is highly susceptible, and a mild form of the disease has been produced in rabbits. Some question exists as to whether cattle, horses, dogs and guinea pigs are susceptible. Rats, mice, chickens and pigs apparently possess natural immunity.[6]

Human infections have occurred in all parts of the world.[3,6-8] Kewish[2] reported that the disease is common in Australia among sheep shearers; he recorded thirty-eight cases over a four-year period, with a total loss of 254 man-hours of work. Schoch[9] reported the first human case in the United States, in 1939. Since then, the disease has been seen frequently among humans in the western and southwestern United States, with occasional cases occurring in the east and midwest.[6,10]

In man, the disease usually is acquired as a result of direct inoculation from infected animals; consequently, it is seen most often among sheep farmers, veterinarians and meat handlers. Isolated lesions occur on the hands, fingers and wrists, with occasional lesions on the face apparently resulting from the transfer of infected material by the fingers. The characteristic lesion is usually a deep-red, moist, soft, dome-shaped nodule with superficial crusting. Bullous and ulcerative lesions occur less frequently. The histologic appearance is characteristic of that associated with acute viral infection (Fig. 2). Without secondary infection, the lesions heal spontaneously over a period of four to eight weeks, with little or no scarring. Constitutional symptoms are usually absent but there may be mild lymphangitis as well as local tenderness and pruritus.[5,7,11]

The disease may not always be mild, however; the German literature includes a report of a generalized vesicular eruption following the primary infection.[12] A British report documents a case of erythema multiforme occurring fifteen days after the development of the initial lesions.[13] Kewish stated that one of his cases of extremely fulminating orf occurred in a housewife in whom multiple lesions developed after she had washed her husband's overalls, which were full of "burrs and grease." In this case, typical lesions developed within twenty-four hours, followed by rigors and drenching sweats, with a temperature of 104.8° F. Improvement was noted after three days, and complete recovery followed. In 1936, Cook[14] reported a case of fatal acute pemphigus occurring in an Australian sheep shearer; it was not definitely established, however, that orf had preceded the acute fatal reaction.

The conditions that most commonly might be confused clinically with orf are impetigo and inflammatory ringworm infections. Vaccinia, tularemia, sporotrichosis and milker's nodules also should be included in the differential diagnosis.

The history is of prime importance when the clinical findings are confusing, because almost all human infections occur as the result of direct inoculation from infected animals.

No specific treatment is available. Since orf is a self-limited disease, the medical management should be directed toward the prevention of secondary infection and the relief of local symptoms. This can be achieved best by the use of antibiotic ointments and wet dressings.

There are no specific laboratory studies that will help in making the diagnosis. As already indicated, the histologic picture is that of an acute viral infection without specific diagnostic features.

Lambs are particularly susceptible to the disease, and the natural infection occurs shortly after the lambs are put to pasture in the spring. A few lambs become infected from the dried crusts containing the viable virus that lie about the pasture from the previous season. The lips, nose and periorbital regions are the sites of predilection. Reddened zones appear first, on which papules, vesicles and pustules develop. These rupture to give rise to a purulent exudate that dries to form brownish-gray crusts.[7] Papillomatous and ulcerative lesions may develop. The lips become swollen, stiff and exquisitely tender. The lamb cannot suckle or graze. It looks miserable and loses weight rapidly. In uncomplicated disease, the crust drops off about the twenty-fourth day, leaving a smooth soft skin without scarring. Systemic manifestations usually are absent. After the disease has developed in a few of the lambs, the infection spreads rapidly throughout the flock as a result of direct contact and contaminated food and water. Ewes which are not immune also will display lesions about the udder, vulva and inner part of the thighs as a result of nursing the infected lambs. After the initial infection, the sheep are highly immune.[1]

Secondary infection with bacteria or infestation with the larvae of the screwworm fly constitutes the most serious aspect of the disease. In such cases, lesions may extend into the buccal cavity to involve the palate, tongue and pharynx. Secondary bronchopneumonia may result in death.[1,15]

A vaccine prepared from the dried crusts is available and is highly effective. Only 0.38 per cent of a large group of vaccinated animals subsequently had the disease, whereas 65 per cent of an unvaccinated control group acquired the infection.[1,15]

Summary and Conclusions

A case of orf in a Minnesota sheep farmer is presented. The course of this viral disease as it occurs in both humans and animals is reviewed. The disease, usually in a benign form, is not uncommon among humans in sheep-raising regions, and it can be easily diagnosed if its history and clinical features are kept in mind. Orf constitutes a serious disease of sheep, influencing the commercial production of lambs. Because it may at times affect those persons engaged in sheep raising, it is an occupational disease of such persons.

Detection of

Fig. 3. Larger hypernephroma.

THERE IS no sure-fire, ironclad, fool-proof method of detecting cancer in the urogenital system. A high index of suspicion is the most important single factor in success; hematuria, pain, the presence of a mass, and obstruction to urination oftenest arouse that suspicion. Ideally, of course, one would detect the growth before it caused symptoms, but that ideal is rarely achieved except in the case of prostate. While early recognition of most lesions of the urinary tract can be achieved now, the elaborate, expen-

sive, and often unpleasant methods required make this impracticable for routine use in "well" patients.

Consequently, one waits hopefully, if pessimistically, for the development of a simple and reliable test for cancer.

Careful questioning, palpation, roentenography, as well as cystoscopic and histologic studies ordinarily will lead to a precise diagnosis.

Malignant tumors of the kidney are divided into parenchymal and pelvic types, with the second of which ureteral growths may as well be considered. Benign lesions large enough to manifest themselves clinically are rare. A *parenchymal tumor* is suspected in any case of hematuria, renal pain, a palpable renal mass, atypical neoplasms of bone, unexplained toxemia with fever and anemia, and unusual polycythemia. The absence of a palpable mass means nothing because the kidney is so well padded by surrounding structures—except in thin people. An accelerated sedimentation rate is a non-specific reaction present in one fourth to one third of these tumors, but is of assistance mainly in deciding the nature of a suspected mass. A neoplasm of the left kidney in the presence of any dyscrasia of the blood is likely to be mistaken for splenomegaly —such a combination should lead one to suspect the kidney.

The diagnosis can usually be made by excretory urography, remembering that globular, encapsulated neoplasms cause pyelographic deformities identical with those of simple cysts. If the excretory urogram is unsatisfactory, a retrograde pyelogram may resolve all doubts (Figs. 1 and 3).

Papanicolau stain of the urinary sediment yields too many negative reports to be really useful, and the cellular pheomorphism of many of these neoplasms is confusing in the stained smear.

Fig. 4. Simple renal cyst.

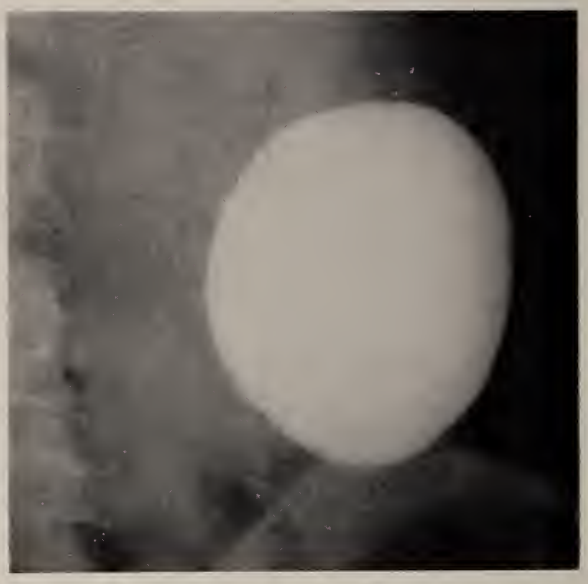

Fig. 5. Cyst injected.

When the pyelographic and other evidence is uncertain, aortography is likely to be conclusive (Fig. 2), although some cite the possibility of serious complications as contraindicating its use. These appear to result from technical errors. Occasionally the aortogram may be misleading if the circulation of the tumor is poor. When the preponderance of evidence favors cyst and the patient is a poor surgical risk, it may be desirable to aspirate the mass and, if clear fluid is recovered, to replace it with contrast agent, thus getting a diagnostic "cystogram" with smooth, sharply defined, rounded margins (Figs. 4 and 5). Irregularities in its margin, the presence of filling defects in the cyst, or inability to aspirate or fill it call for surgical exploration.

Pelvic and ureteral tumors produce palpable masses only when so situated as to cause large hydronephroses, or when they infiltrate the ureter in a palpable area (vagina, rectum). However, virtually all of them are readily identifiable on excretory or retrograde pyelography, usually undertaken because of hematuria (Fig. 6); one must remember that both pelvis and ureter may be involved simultaneously. Aortography is of no value because these tumors are relatively avascular. The Papanicolau stain is more likely to be positive than in parenchymal tumors because the lesions are bathed by the urine, but negative tests are of no value.

Fig. 6. Papillary epithelioma.

Fig. 7. Wilms' tumor.

Wilms' tumors are always suspected in infants and children, particularly under the age of two years, in the presence of a smooth, firm abdominal mass in the region of the kidney. There are many who contend that the presence of an abdominal mass in childhood constitutes a surgical emergency. This is objectionable, to put it mildly, because the general application of this policy by those not competent in urological diagnosis has led to such tragedies as the removal of a solitary kidney, and to such gross blunders as the excision of a salvageable hydronephrosis, et cetera. The advocates of this policy remind me of slightly addled Sir Galahads leaping upon their white chargers and riding off in all directions at once without regard for the consequences—exciting, but not an exhibition of good judgment.

Excretory urography ordinarily suffices for diagnosis, but may have to be supplemented by retrograde pyelography, for which there is always time available (Fig. 7).

In the infant, one should always try to transilluminate the mass with a small source of intense light, such as is provided by a cystoscope bulb, in a completely dark room; if the light shines through, the mass is not a neoplasm, and any idea of urgency can be abandoned.

Tumors of the urinary bladder usually cause hematuria, and are rarely identifiable by physical examination, unless they infiltrate the base of the bladder so as to be palpable on bimanual pelvic or rectal examination. Excretory urography, which should *always* be done in the presence of hematuria or vesical irritation, will be normal if the tumor is too small to displace a visible amount of contrast agent. Larger ones produce central or peripheral filling defects (Figs. 8 and 9), but cystoscopic biopsy is always necessary for definitive diagnosis, regardless of roentgenographic appearances. The cystoscopic examination should be done under anesthesia so that one will not be tempted to hurry because the patient is being hurt, and because the relaxation facilitates adequate bimanual examination. Soft lesions are biopsied with cystoscopic forceps, but hard ones call for the resectoscope so that a generous sample can be removed; it should include part of the base and an edge of the tumor.

Fig. 8. Vesical papillomata.

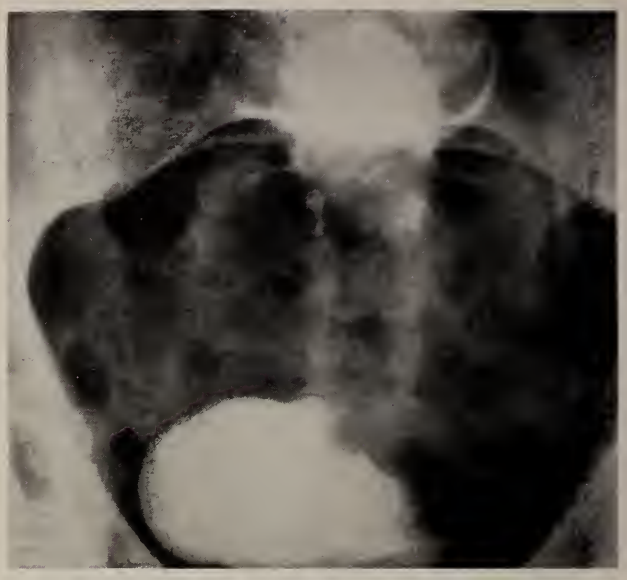

Fig. 9. Vesical carcinoma.

In the case of the *prostate gland,* urinary symptoms are nonspecific; both cancer and benign hypertrophy cause the same kind of obstruction. Suspicion is aroused by troublesome sacral backache (mestastasis) and sciatic pain (local infiltration). The significant physical finding is stony induration, whether in the form of a small nodule, or of extensive invasion, enlargement, or fixation.

acceptable evidence that the "prostatic" phosphatase is more sensitive than the standard test. If the acid phosphatase level is equivocal in the presence of suspicious findings, it may sometimes be made to rise by the intramuscular injection, on alternate days, of a series of several 25-mg. doses of testosterone propionate. Roentgenograms of the lumbar spine and pelvis may show the typical osteoblastic or the uncommon osteoclastic

Fig. 10. Osteoblastic metastases.

If the tumor has metastasized, the serum acid phosphatase will be elevated in from 70 to 80 per cent of the patients. There is as yet no

metastases (Figs. 10 and 11). If these and a definitely elevated acid phosphatase are found together, the diagnosis is definite.

Fig. 11. Osceolastic metastases.

The isolated nodule without other manifestations requires biopsy. If the lesion is fair-sized *and no curative operation is contemplated,* needle biopsy is useful, but fails oftenest where most needed, that is, the smallest nodules are the hardest to sample. Transrectal biopsy with a special punch has become popular, but I do not believe that it should be used for potentially curable lesions, lest the definitive operation be followed by a recto-urethral fistula. It is, however, handy for inoperable lesions where tissue must be secured before castration, an operation which should not be used in cancer of the prostate without absolute proof of malignancy.

Open biopsy should be used with small isolated nodules in patients under seventy and in good condition, and should be followed at once by total prostatovesiculectomy if the frozen section is positive, because this operation yields fifty per cent of durable cures. The Papanicolau stain of the expressed prostatic secretion has been advocated as a diagnostic method, but positive results are relatively infrequent, and there is grave doubt as to the propriety of massaging a suspected cancer.

Cancer of the urethra is rare in both sexes. In the male it manifests itself oftenest as rather profuse bleeding after dilatation of an old stricture. A hard lump is then palpated along the course of the urethra, and biopsy, usually with the urethroscope or through an incision, discloses the nature of the lesion. Urethrography may show a mass with ragged margins intruding into the urethral lumen but is not absolutely diagnostic.

In the female, attention may be drawn to the disease by a little dysuria, perhaps with scanty bleeding. A "caruncle" which bleeds or is firm to hard in consistency should be excised *in toto* for microscopic examination. Either urethral bleeding or induration along the canal calls for urethroscopic examination with biopsy of any area of thickening, induration, or ulceration. The resectoscope will permit securing a deep specimen. Since parts of the cancer may be covered by intact epithelium, a deep sample is essential (resectoscope).

All chronic ulcers and papillary lesions of the *glans penis* should be viewed with grave suspicion, as should induration beneath an adherent foreskin. Small visible lesions should be excised completely for biopsy (Figs. 12 and 13). A deep

Fig. 12. Papillary carcinoma penis.

wedge should be removed from larger ones. One assumes, naturally, that chancres will not be treated in this fashion. An adherent foreskin with subjacent induration should be slit on the dorum to permit inspection and biopsy of the underlying tissue.

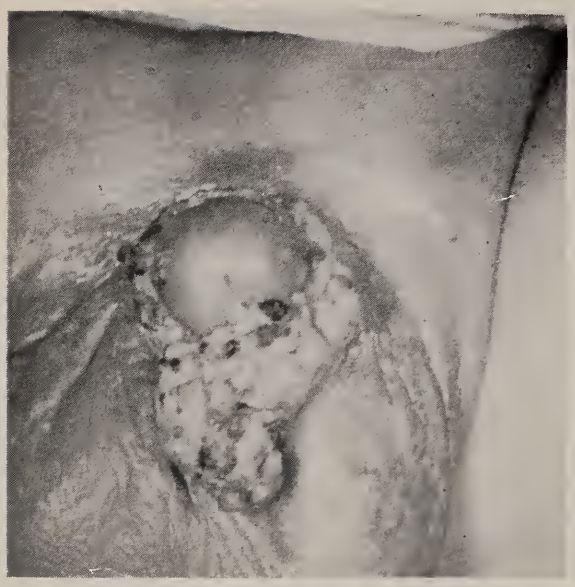

Fig. 13. Infiltrating carcinoma of penis.

The identification of *testicular neoplasms* is ordinarily relatively easy. In the average case there is a painless, insensitive, rather heavy, firm to hard, smooth or lobulated mass which usually retains the general shape of the testis. It cannot be transilluminated. Differential diagnosis in such a situation includes thick walled hydrocele, hematocele, tuberculosis of the epididymis, spermatocele, and gumma (I have never encountered one except in the pathological museum). One must be on the alert for the patient who is a poor observer and who says that his swelling came on abruptly while he was straining to defecate, or after a minor trauma.

Small localized nodules give more trouble, especially if they adjoin the epididymis and are a little tender. Spermatocele, spermatic granuloma, and localized epididymitis come into question. Spermatocele and hydrocele are readily identified by their consistency and by the fact that they can be transilluminated. The others may require exploration for final diagnosis (Fig. 14). The incision begins above the external ring and extends onto the upper scrotum. The spermatic cord is isolated and compressed with a rubber shod clamp while the testicle is extracted from the scrotum. If its appearance is not diagnostic, the tunica is opened; inspection will usually suffice for diagnosis. Biopsy of suspected testicular neoplasms is to be avoided because the growth potential is so great that local implantation of the tumor in the wound is probable. The Ascheim-Zondek and other pregnancy tests are of value only if positive; they are too often negative.

Fig. 14. Small testicular tumor.

Neoplasmas of the epididymis are rare. Most are benign, but those found in the testis also appear here. They are identified by their location; their consistency is like that of those in the testis. In general, a discrete nodule in the epididymis is best exised and subjected to frozen section diagnosis while the wound is protected from contamination.

Tumors of the spermatic cord are also uncommon. (I have seen one large lipoma). Consistency is that of lipomata elsewhere, and they are best identified by surgical exposure. Since the cord also contains muscle, connective tissue, and blood vessels as well as nerves, there are many other possibilities, recognition of the character of which depends upon microscopic study.

Summary

Detection of cancer in the genitourinary tract is a matter of suspicion followed by painstaking (and sometimes repeated) investigation. It is better to take the time necessary for accurate diagnosis than to leap to unwarranted conclusions.

Hypertension due to UNILATERAL RENAL DISEASE

J. ALLEN WILSON, M.D.
FREDERICK E. B. FOLEY, M.D.
Saint Paul, Minnesota

GOLDBLATT and others,[1] in 1934, showed that partial constriction by a metal clamp of both main renal arteries of dogs regularly resulted in persistent hypertension. Page[2] later produced chronic hypertension by investing both kidneys in cellophane. Others have produced similar effects by wrapping the kidneys in silk, tape, collodion or latex, producing an inflammatory reaction which constricts either the pedicles or the kidneys and behaves like renal artery constriction.

Complete denervation of the kidney or transplantation of the kidney to another part of the body does not interfere with these effects of ischemia—thus, the mechanism is a humoral one. Goldblatt also found that if the renal vein is obstructed at the same time the artery is constricted, no hypertension develops. Extracts of rabbit kidneys thus made ischemic have yielded on extraction a pressor substance called renin by Tigerstedt and Bergman.[3] Injection of this substance into other rabbits produced a sustained rise of blood pressure. Houssay and Taquini[4] found that the kidney is the only organ which when made ischemic is a source of the pressor substance. Normal kidney tissue has the ability to destroy or eliminate this pressor substance. Thus, if clamping one main renal artery leads to a moderate rise of blood pressure which tends to decline slowly, removal of the opposite normal kidney is followed by a prompt increase of blood pressure to the previously high level. All attempts to demonstrate the presence of this substance in the blood of hypertensive animals and man have been unsuccessful. Pickering[5] quotes several experimenters as finding a pressor substance in the renal vein blood after recent constriction of the renal arteries—they called it hypertensin. Renin is formed from the cortex layer of the kidneys—probably the tubules. It acts as an enzyme splitting

Read before the Minnesota Society of Internal Medicine, Minneapolis, May 16, 1959.

Fig. 1. Intravenous pyelogram showing good filling of the right renal pelvis and calyces and little if any filling on the left side.

Fig. 2. Retrograde pyelogram showing normal retrograde filling of the left pelvis and calyces.

off hypertensin or angiotonin from a portion of plasma proteins called hypertensinogen.

In animals and man, where hypertension originally caused by ischemia of one kidney was allowed to continue for some time, removal of this kidney did not cure the hypertension. Some other mechanism then is called into play—with perhaps permanent damage to arterioles.

Wakerlin,[6] Johnson and Goldblatt showed that an anti-renin formed by injection of heterologous renin into dogs, prevents hypertension from renal artery constriction, or abolishes it if already established for a short time.

The clamped kidneys, due to reduced blood flow, are spared from the arteriolar changes noted in the opposite kidney resulting from the sustained hypertension.

Removal of the anterior lobe of the pituitary abolishes the hypertension due to renal ischemia, as does also total adrenalectomy. However, Pickering[5] states that there is no evidence that there is an increased secretion of adrenal cortical hormone to account for the chronic phase of hypertension secondary to renal artery constriction.

Braasch[7] reported that only 2.5 per cent of 4,000 hypertensive patients had a renal lesion and in only one-fifth of these did the disease present surgical potentialities.

In man, it must be proved that the renal disease antedated the hypertension and that the removal of the affected kidney produced return of blood pressure to a normal range well beyond the postoperative period. (One should allow one year to pass after surgery before claiming benefit from

the nephrectomy.) Hypertension has been reported relieved by nephrectomy for tumor, calculus, tuberculosis, hydronephrosis, unilateral pyelonephritis, and vascular lesions of the renal artery.

Recurrence of hypertension has occasionally been reported as late as three and one half years after some of these nephrectomies. Of 318 cases of nephrectomy for unilateral renal disease associated with hypertension which were reported in the medical literature up to 1954, 287 were followed over one year and seventy-seven patients were reported as "cured" of their hypertension. Of these, thirty-three had chronic unilateral pyelitis. Drs. Creevy and Reiser[8] at this University, in 1954, reported eight patients with unilateral renal disease with hypertension who underwent nephrectomy. Two of these had been normotensive for at least one year. They stated that there is no reason to believe that unilateral congenital renal hypoplasia can produce hypertension.

Reiser and Creevy[8] state that surgery for hypertension in patients with unilateral renal disease should be carried out only if:

1. There is a surgical indication for removal of the diseased kidney.

2. There is a non-functioning or poorly functioning kidney.

3. The contralateral kidney is hypertrophied and capable of sustaining life.

4. The hypertension has been present on several determinations.

5. The blood pressure elevation is of less than two years' duration.

6. There are no secondary irreversible hypertensive changes in other organs which in themselves make the patient inoperable.

The tests to be done before surgery should be: (1) intravenous urogram; (2) cystoscopy and retrograde pyelograms; (3) phenosulfonphthalein determinations for each kidney; (4) bacteriologic examination of each kidney; (5) aortography in some doubtful cases.

The prognosis is the best under the age of forty, especially in children where no vascular lesions have occurred in the opposite kidney.

Report of Case

Mr. B. L., aged forty-five, was first seen on August 24, 1956. Two weeks earlier, he had an episode of acute pulmonary edema. He was rushed to a hospital in Onamia, Minnesota, and placed in an oxygen tent. His blood pressure on arrival at the hospital was 290/140. Later it dropped to 210/120.

This man had passed an insurance examination one year prior to this incident at which time his local physician had reported a normal blood pressure. He had led an active life, selling fire-fighting equipment. He had not experienced headaches or vertigo.

His doctor at Onamia had obtained an intravenous urogram which showed nonfunction of the left kidney. The doctor referred him to Dr. Frederic Foley of St. Paul for investigation of his renal status.

Physical examination revealed minimal arteriosclerosis of the retinal vessels, without scars or fresh hemorrhages. His heart was at the upper limit of normal size. A2 was greater than P2. The patient was admitted to the Miller Hospital to rule out the presence of pheochromocytoma and/or the presence of unilateral renal disease.

His urine gave a 1 plus albumen reaction but no abnormal cells or casts.

The intravenous P.S.P. test gave 30 per cent excretion of dye at 15 minutes and 15 per cent at 30 minutes. BUN was 17 mgm. per cent. Sedimentation rate was 27 mm. BMR was plus 4 per cent. Fasting blood sugar was 130 mgm. per cent. Hemoglobin 16.2 gms. Red blood cell count was 5.03 million per cu. mm.; white blood cells, 10,850. Bromsulfthalein retention was 5 per cent at 45 minutes. One Benodaine and three Regitine tests gave normal or borderline findings.

An intravenous urogram showed no excretion of dye by the left kidney (Fig. 1). Two days later, Dr. Foley interpreted a retrograde pyelogram on the left (Fig. 2) as normal and from these two findings he diagnosed an infarcted left kidney. Three days later, a repeat intravenous urogram showed slight function in the left kidney (about 20 per cent).

The patient's blood pressures meanwhile were recorded in the range of 184/120 to 200/130.

A ureteral catheter was left in the left ureter, and for three successive days the output from this kidney was recorded as 30-150 and 300 cc. compared to a total urine excretion of 2500-3000 cc. for those days.

On September 12, the patient was allowed to go home, presumably to return in a month for re-evaluation of this left kidney function. One week later, his local physician found his blood pressure 196/128. Further readings of blood pressure at home in the following week were in the range of 190-200 systolic and 120-130 diastolic. He re-entered Miller Hospital on September 25 and on the next day a left nephrectomy was carried out by Dr. Foley.

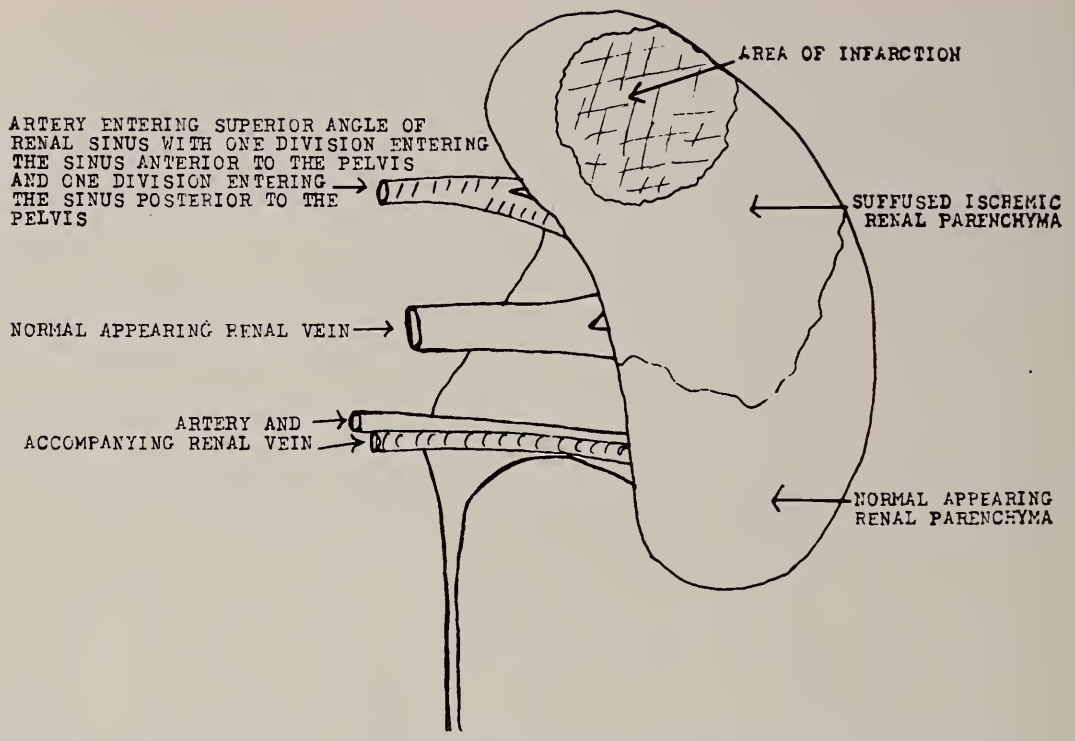

Fig. 3. Diagram showing infarcted upper three-fourths of left kidney due to thrombosis of left main renal artery. The viable lower one-fourth of this kidney was served by an aberrant artery arising lower on the aorta.

At surgery (Fig. 3), Dr. Foley found the main left renal artery closed by a thrombus at the site of an arteriosclerotic plaque, and the upper three-quarters of this kidney was infarcted. A definite line of demarcation separated the infarcted portion from a viable lower quarter of the kidney which was supplied by an aberrant smaller renal artery arising at a lower level of the aorta.

The patient's postoperative blood pressure averaged around 120/80, and on leaving the hospital on October 3, 1956, his blood pressure was 140-150 systolic and 90 diastolic. A month later, his local doctor read the pressure as 120/80.

The man has since had other vascular difficulties, with vascular insufficiency of his internal iliac vessels. On August 27, 1957, he was operated on at the Miller Hospital by Dr. Davitt Felder for a right common iliac obstruction. An aortofemoral arterial by-pass was performed. His blood pressure on that admission was 160/80. On October 18, 1957, he was admitted to the Miller Hospital for aortography. His blood pressure then was 150/90. On January 30, 1958, he was admitted to the hospital again for endarterectomy and sympathectomy for a right common iliac obstruction. His blood pressure on admission was 172/100. Later readings before leaving the hospital were 110/90 and 130/80.

The authors wrote to the patient recently and asked him to have a blood pressure reading by his local doctor. It was 144/82. The patient is able to carry on moderately limited work. His only disability is the circulation to his right lower extremity.

Conclusion

A brief discussion of, and a case report demonstrating hypertension due to unilateral renal disease, have been presented. The criteria for assigning the cause of hypertension to unilateral renal disease are rigid, but the authors think that this case meets these criteria.

Report of Case

Diverticulitis of the CECUM

OLIVER E. H. LARSON, M.D.
Zumbrota, Minnesota

DIVERTICULITIS of the cecum is rare. The true incidence is not known. Reports of acute diverticulitis of the cecum are not common in the literature, and until January 1959, there were about 200 such cases reported. Of 900 operations for colonic diverticulitis at the Mayo Clinic, nine were in the cecal area. It is probably more common than reported, however, because half the cases constituting the report given by Nissenbaum[1] were found by only twenty-two authors. Also, nearly half of the cases of this same series was reported within the last five years.

Cecal diverticulae differ from the generalized form in that they are usually single. They occur in a much younger age group and generally are of the true variety. It is generally accepted that they are congenital.

The diverticulae are approximately 1 cm. in diameter at the osteum and vary from 1 to 3 cm. in length. Most of the cases contain fecaliths which cause the obstruction which is believed to be responsible for the onset of the inflammatory reaction.[2] The acute inflammatory stage, as expected, is characterized by hyperemia, leukocytic infiltration, suppuration, ulceration, and possibly gangrene with adjacent pericecal edema and peritoneal reaction. Subsequently the process may resolve with recurrent low-grade localized infection. On the other hand, the acute processes may proceed to perforation with either localized abscess or a generalized peritonitis resulting. If the condition extends beyond the diverticulum, it involves the adjacent cecum and pericecal tissue, and a large inflamed granulomatous mass with palpable mesenteric lymph nodes, indistinguishable from infected carcinoma confronts the surgeon at laparotomy. The majority of the cecal diverticulae are located close to the iliocecal valve. A cecal diverticulum is rarely, if ever, found in an appendix epiploica, in contra-distinction to those found in the sigmoid colon.

The diagnosis of diverticulitis of the cecum is rarely made prior to operation. The most common diagnosis in almost 100 per cent of the cases being acute appendicitis, and the abdomen is opened with this diagnosis in mind. The symptoms and signs of acute diverticulitis are practically indistinguishable from those of acute appendicitis. Nausea and vomiting seem to be more frequent with appendicitis than with diverticulitis. A right lower quadrant mass was palpable in

about one third of the cases reported. The average age is 39.6; distinctly less than the average age of 53.6 quoted for diverticulitis of the sigmoid colon. The sexes are about equally affected.

In about 65 per cent of the cases it is possible to make a correct diagnosis at laparotomy; in the remaining cases it is impossible to tell if one is dealing with a malignancy or not. Cecotomy has been used and found to be very valuable in making a diagnosis at the time of operation. A flat plate of the abdomen is considered by some to be valuable pre-operatively in making a diagnosis. In some cases, a correct diagnosis was obtained preoperatively, by the use of barium enema. In the cases reported by Inglis[2] two of them were given barium enemas preoperatively, but the diagnosis was not evident because the diverticulae were filled with fecal material. When confronted with a mass at laparotomy, the differential diagnoses to be considered include: carcinoma, tuberculosis, actinomycosis, non-specific granulomas including regional ileitis and the non-specific ulcer; and to these might be added the carcinoid tumor and the subacute foreign body perforations of the cecum.

It is generally agreed that local excision of the lesion is the best form of treatment. Right hemicholectomy was performed in six of sixteen operations in the series reported by Inglis.[2] They considered that major colonic resections could have been avoided if the true nature of the condition had been realized at the time of operation. However, these authors point out that there are circumstances when a major colonic resection is necessary because the diverticulum is so close to the iliocecal valve or the diverticulum is in such a position as to jeopardize the blood supply of the colon. In all cases except those of hemicolectomy, the appendix was removed at the time of the primary treatment of the diverticulum. This did not appear to increase post-operative morbidity and it is recommended that appendectomy accompany the local excision of the diverticulum.

In summary, acute diverticulitis of the cecum, although relatively rare, probably occurs more commonly than standard surgical texts or the surgical literature would suggest. It is generally not possible to distinguish it from acute appendicitis on a clinical basis. At operation, the diagnosis is evident in about 65 per cent of the cases. In the remaining instances, it is concealed in a mass which is usually interpreted as carcinoma. Colotomy is a valuable means of establishing the diagnosis at the time of surgery. Local excision of the lesion and in some cases simple inversion of the diverticulum constitute the treatment of choice. Appendectomy may and should be carried out concurrently if at all feasible. Major colonic resections can usually be avoided if the possibility of diverticulitis of the cecum is considered. Anyone doing appendectomies should be aware of this lesion and know how to deal with it. And, when a laparotomy is performed for a preoperative diagnosis of appendicitis, and a normal appendix is encountered the cecum as well as the gall bladder and the terminal ilium and the pelvic viscera, should be explored carefully.

Case Report

Mr. G. H., aged twenty-seven, white, is married and is a tavern owner. He became ill on May 4, 1959, in the afternoon. He noted pain in the abdomen, on the right side. This pain was steady in character. The pain had started on the right side, and had stayed there throughout his present illness. He was seen in the out-patient department of the Zumbrota Hospital at 9:00 A.M. on May 5, 1959, and found to have tenderness a little above and a little lateral to McBurney's point, and there was a suggestion of a mass. The urine was negative. The white count was 14,850 with 78 neutrophiles, 20 lymphocytes, 1 monocyte, and 1 basophil. The patient was sent to Dr. Sam Hamilton of Red Wing, for consultation. Doctor Hamilton saw him on May 5, 1959, in the early part of the afternoon, and agreed that the most likely diagnosis was appendicitis and that surgery was indicated. He also reported that he could feel a mass. The patient was brought back to the Zumbrota Community Hospital for surgery.

Family History: The father had his stomach removed for a duodenal ulcer. Otherwise there is no history in the family of any unusual intestinal trouble.

Past History: Patient has had no severe illnesses. He has had no previous abdominal surgery. He was injured in an automobile accident in 1951, and his left arm was operated on for fracture of both bones of the forearm.

Physical Examination was as follows: Blood pressure: 118/64; temperature: 100.6 orally; pulse: 94, respirations: 26. The positive findings were confined to the abdomen. There was a suggestion of a mass a little above and a little lateral to McBurney's point. There was marked tenderness and rebound tenderness at this point. Bowel sounds were present.

Preoperative Diagnosis: Acute appendicitis.

The patient was operated on at 4:00 P.M. on May 5, 1959. The usual muscle-splitting incision was made over the point of most tenderness. The appendix appeared to be normal. Immediately adjacent to it within one half inch of the base of the appendix, was a mass measuring about one and one-half inches in diameter.

This mass was hard and indurated, and covered with fibrin. Diverticulae could be seen along the course of the cecum. At one point in the inflammatory mass, after delivering the cecum, fecal material could be seen oozing out. A tentative diagnosis of diverticulitis was made; however, cancer could not be ruled out. The appendix was removed in the usual manner, and it was decided to exteriorize the cecum because of the perforation, and to do a secondary operation later. It was felt that in this manner we could get an assessment of the entire colon and prepare the bowel before we did a definitive operation. The cecum was brought out and the peritoneum was closed around it. The fascia and subcutaneous tissue were closed with catgut sutures. Skin clips were used in the skin. The patient was placed on I.M. penicillin 400,000 unit and dihydrostreptomycin ½ gm. b.i.d. for five days. He was treated with continuous gastric suction for two days, and with intravenous feedings during this time. On May 12, 1959, a barium enema was done, and reported that the mucosal pattern of the cecum was normal, and there was no evidence of any intrinsic mass. There were several diverticulae seen in the cecum and the proximal ascending colon.

During the week after the original surgery, there was some leakage of fecal material from the exteriorized cecum with its mass, some leakage being noted on May 7, 1959, and on May 8, and again on May 12. His general condition became very good a few days after the original surgery and he was able to be up and around. From May 11 until May 13 he was given Neomycin 1 gm. every hour for four doses, and then 1 gm. every four hours, and also given cleansing enemas.

On May 13, 1959, he was again operated on and under general anesthesia the cecostomy was taken down and a right hemicolectomy was done. The main incision was closed in the usual manner without a drain. The cecostomy wound was closed leaving a drain in the wound after the peritoneum was closed. Following the hemicolectomy, he was again put on penicillin-dihydrostreptomycin, b.i.d, for five days. On May 20, 1959, the patient started running a higher temperature, going up to 101.8 in the afternoon. This was occurring after the temperature had apparently settled down near normal. He was examined, and a chest x-ray was taken which showed patches of atelectasis in both bases but otherwise was normal. On May 22, the temperature having stayed up, Tetracycline HCl and Glucosamine 250 mg., four times a day, was started, and the patient began to improve within a day or two. On May 23, 1959, two small areas on the main incision broke open and drained purulent material. This drainage, however, stopped within twenty-four to thirty-six hours, and these areas promptly healed up. They seemed to be superficial small wound abscesses. The fact that the fever went down and the patient felt better after they opened and drained, suggested that they were the cause of his secondary rise in temperature. The sutures and drain were taken out of the cecostomy incision on May 25, and the patient left the hospital on May 27, twenty-two days after his original admission. He has been well since. The pathology report after the first operation was as follows:

"The appendix is 9 cms. long, smooth, and shows no active inflammation." The pathology report following the hemicolectomy was as follows: "The specimen consists of a segment of terminal ilium about 6 cm. long together with a segment of the cecum 9 cm. long. The surfaces, particularly the base of the cecum, are roughened and covered with hemmorhagic partly necrotic exudate. What is probably a short segment of appendix is buried in the indurated fat in one area in the base of the cecum. Microscopic section here shows inflammatory changes and scarring around this structure. There is no evidence to indicate that this process began in the lumen. In the vicinity there are several diverticulae of the cecum. There are extensive inflammatory changes and scarring in relation to these structures. I have not with certainty demonstrated the point of origin of the inflammatory changes, but in all probability it began as a diverticulitis."

Summary

Here is presented a case of acute diverticulitis of the cecum in a young person. It was discovered at the time of laparotomy which was done with the preoperative diagnosis of acute appendicitis. We were not able to be sure of the diagnosis at the time of the first laparotomy. However, the young age of the patient made a carcinoma unlikely. The procedure of exteriorizing the cecum with its mass seemed very reasonable, and seemed to be the safest thing to do at the time. The patient got along very well and had no complications of any serious consequence. In our patient, the diverticulum was not a solitary diverticulum of the cecum, there being about five or six of them present. The rest of the colon did not have a diverticulum or any pathology. The hemicolectomy was done to excise the inflammatory mass and also the other diverticulae present in the area. The young age of the patient suggests that they were congenital in origin.

Applied Anatomy for Ptosis Surgery

FRANK ADAIR, M.D.
Saint Paul, Minnesota

THERE ARE few operations that give more satisfaction to the surgeon than the successful correction of muscular deformities about the eye.

And there are few patients who are more lastingly grateful to their surgeons than those who have had such deformities corrected.

There is something about visible ocular defects that is different. Human nature being what it is, a limp or a brace or a deformed back will evoke silent pity, while a crossed eye or a drooping lid will excite ridicule.

The child whose eyes cross must learn early in life to parry the question, "Who are you looking at, anyway?" and to ignore the greeting, "Hi, Cockeye!" To be called "Droopy" or "Blinky" is all too familiar to the child with a ptosis of the upper lid. These cruel words cut like a knife into the heart of a child. It is important that the conditions which provoke them be corrected before he is old enough to have them endanger his personality.

But it is even more important that their surgical correction, once undertaken, be done well. This is only possible when the surgeon has a thorough, complete, and detailed knowledge of the anatomy involved. This is particularly important in the matter of ptosis of the upper eyelid.

Resection of the levator muscle is the most frequently employed technique for correcting ptosis of the upper eyelid. Provided the operator thoroughly understands the anatomy of the levator muscle and the related fascial planes, this operation is safe, simple, and usually successful.

In conjunction with Dr. Walter Fink, in his work on the oblique muscles, I have recently reviewed and dissected the upper orbital structures.

It is hoped that the following anatomical review will be useful to some of you, as it has been to me, at the operating table.

Notes on Embryology

The four recti muscles, with the obliques, separate out from the mesodermal cone at the two-months, or 20-mm. stage, of embryonic development. The levator appears much later as a small muscle slip separating from the medial border of the superior rectus. At the 75-mm. stage, it overlaps the superior rectus and grows rapidly forward, but does not reach its final position until the fourth or fifth month of fetal life. This late appearance of the levator may account, in part, for some of its congenital weaknesses.

Anatomy of the Levator

The levator palpebrae superioris muscle is the special elevator of the upper eyelid. By contraction of this muscle's belly, the transverse aponeurosis is pulled back over the globe, pulling with it the skin of the lid, the tarsal plate, and the loose conjunctiva of the superior fornix.

It acts in harmony with the superior rectus with which it shares the same nerve supply, though it may act independently. It can also act

in unison with the frontalis muscle, as in expression of amazement. All three muscles act together in looking up.

The levator muscle is thin, flat, and roughly in the shape of an isosceles triangle. It arises by a short tendon from the lesser wing of the sphenoid bone just above the annulus. Its origin blends inferiorly with the superior rectus and medially with the superior oblique. It passes forward close beneath the roof of the orbit, the frontal nerve and the supra-orbital artery lying upon it. From the beginning, the levator lies upon the superior rectus, the medial borders of the two muscles being adherent by a thin fascial sheath.

As the muscle approaches the septum orbitale, it terminates in a smooth glistening expanded aponeurosis. This aponeurosis is shaped like a visor and splays forward to become attached primarily to the skin of the whole of the pre-tarsal part of the lid. The lateral extremities of the aponeurosis remain tendinous and form the two horns which attach to the bone at the lateral and medial orbital margins.

The lateral horn is the stronger, and after cutting into the lacrimal gland, it inserts at the orbital tubercle of the zygomatic bone. The medial horn passes over the tendon of the superior oblique and fuses with the medial palpebral ligament to attach to the lacrimal bone.

The secondary attachments of the levator are to the upper margin of the tarsal plate and to the conjunctiva of the upper fornix. The former is accomplished by the superior palpebrae muscle of Muller, and the latter, by slips of the fascial sheath of the muscle's belly.

Related Fascial Sheaths

The fascial sheath of the levator is thin posteriorly. The anterior part of the sheath, just behind the aponeurosis, becomes thick and spreads transversely across to reach the orbital walls on either side. This horizontally displaced sheath lies above the aponeurosis and is said to be the true check ligament to the levator, preventing its overaction.

The septum orbitale, or tarsal ligament of Winslow, is membranous and quite thick at its origin along the periosteum of the orbital margin. Its fibers pass downward to fuse with aponeurotic fibers and are carried forward with them to attach to the skin of the upper lid. This disposition of septum fibers aids in forming the external palpebral fold when the lid is elevated.

Practical Anatomical Considerations at Time of Surgery

1. One should make a good dissection of the aponeurosis, picking up the glistening white ribbon over as wide an area as possible. The tongue for resection should be at least as wide as the "Berke" ptosis clamp, which is 14 to 15 mm.

2. Be sure to identify the orbital septum. It appears as a thin white fascial wall falling perpendicularly onto the upper part of the aponeurosis.

3. Resect enough of the muscle. It is easy to take 14 mm., or more, and this would rarely be too much.

4. When re-attaching the muscle, space four to six mattress sutures so that the cut end can be spread out to conform to the lid margin from the medial to the lateral extremities, just as the natural aponeurosis splays horizontally.

5. Pass each suture through the orbital septum, being careful to take the bite high and near the periosteal attachment at the upper orbital rim. This copies the natural attachment and gives the lid a well formed palpebral fold.

6. Bring the sutures out low, near the cilia, and spaced across the entire margin of the upper lid. This is the area of the primary and main insertion of the terminal cutaneous fibers of the levator.

7. Try using one of the operations in which the conjunctiva of the upper fornix is shortened and pulled up with the sutures, such as the Iliff operation. One of the secondary points of insertion of the levator sheath is into the conjunctiva.

Summary

1. The gross anatomy of the levator palpebrae superioris is reviewed.

2. Some practical points of the applied anatomy for ptosis surgery are listed.

Cutaneous Manifestations of

ELMER M. HILL, M.D.
Minneapolis, Minnesota

CUTANEOUS changes associated with internal cancer and the malignant lymphomas interest not only dermatologists but also internists, surgeons and other practitioners. Frequently, the cutaneous manifestations of these diseases are typical, both clinically and microscopically. In some cases, however, the cutaneous signs and symptoms are not characteristic, but only suggestive of the underlying internal disorder. Sometimes, they represent the initial symptom noted by the patient. Early recognition and accurate interpretation of these dermal clues will often aid the physician in his search for the internal counterpart.

Since it is obviously impossible to discuss in detail all the cutaneous manifestations of internal malignancy, a brief review of the more common cutaneous findings occurring with these conditions will be given. It has been customary to classify the various skin lesions observed in association with internal neoplastic disease into two groups, specific, and non-specific or toxic. In the specific group, the malignant process involves the skin directly and the lesions represent true neoplastic infiltrations. The non-specific or toxic eruptions may consist of a variety of localized or generalized primary cutaneous lesions including macules, papules, vesicles, bullae, wheals and hemorrhagic lesions. Also localized erythema frequently becoming generalized and associated with scaling is fairly common. This is referred to as exfoliative erythroderma. Excoriations and secondary pigmentary changes are also frequently seen. However, it should be emphasized that the designation non-specific is purely a morphologic one, since specific tumor infiltrates are frequently present in these lesions also and the differentiation thus depends on the microscopic features. In some instances, there is no sharp dividing line between the two types of lesions.

Visceral carcinoma may rarely metastasize to the skin either early or more often, late in the course of the disease. The incidence of cutaneous

Inaugural Thesis presented before the Minneapolis Academy of Medicine, April 21, 1958.

Internal Malignancy

metastases has been reported as being from 1 to 3 per cent.[1] In an autopsy study of 2031 cases of internal cancer,[2] Gates found fifty-eight instances of cutaneous metastases, an incidence of 2.8 per cent. McDonald, Heckel and Kretchmer,[3] in a review of the Chicago Presbyterian Hospital records from 1903-1949, found only thirty-three cases of cutaneous metastases in a series of 11,265 cancer patients. Of these, the primary occurred in the breast in nineteen, rectum five, stomach two, bladder two, and one each in the sigmoid, uterus, ovary, parotid and thyroid. Cutaneous metastases from cancer of the lung, kidney and prostate have been reported by several authors. The metastases reach the skin either by direct extension or by dissemination through the lymphatics or blood stream. The most frequent sites of involvement are the scalp and trunk, although lesions may occur on any part of the skin. The tumors may be single or multiple, firm, discrete nodules of variable size and color. They are usually asymptomatic, and since they have no characteristic clinical appearance, microscopic examination is necessary for a diagnosis. Rosenthal and Lever,[4] in a review of the literature on sixty-nine patients with cutaneous lesions from kidney cancer, found forty-four instances of true metastases, sixteen of extension to the nephrectomy scar and nine had extension to the external genitalia, five of these in the male and four in the female. In fifteen patients, the scalp was the site of metastasis and in 20 per cent the cutaneous lesions were recognized before a diagnosis of the primary kidney tumor was made. Malignant disseminating tumors of the breast rarely produce an erysipelas-like inflammatory skin reaction or an infiltrating plaque-type of carcinoma which usually involves the chest wall (carcinoma en cuirasse). Similar lesions have also been reported with carcinoma of the stomach and carcinoma of the rectum.[5]

Non-specific cutaneous manifestations occurring in association with visceral cancer are variable and quite rare. Usually, they indicate necrosis of the tumor and represent a late feature. The most common cutaneous eruption, according to Bluefarb,[6] consists of pruritic, grouped, papular, urti-

carial and vesicular lesions which are clinically suggestive of dermatitis herpetiformis. Many instances of this type of eruption occurring with internal carcinomas have been reported. The skin eruption usually clears when the tumor is removed. Severe generalized pruritus may often be an early premonitory symptom of internal cancer. Many instances of breast, intra-abdominal and rectal carcinomas have been reported in which pruritus preceded all other symptoms and subsided promptly following removal of the primary tumor, only to reappear when the tumor recurred. Pruritic papular eruptions associated with hyperpigmentation have also been noted. The melanoderma may be due to the itching and trauma of scratching or may indicate adrenal involvement by tumor tissue or by pressure. Another pigmentary disturbance known as malignant acanthosis nigricans occurs in conjunction with highly malignant internal adenocarcinoma, the majority of which (about 92 per cent) are intra-abdominal, usually in the stomach. About 8 per cent of the lesions originate in the breast or lung.[7] In this disorder the cutaneous picture precedes the signs and symptoms of the cancer in about 20 per cent and in some instances this has been by several years.[8] In other cases, the eruption has coincided with, or followed, the appearance of the carcinoma. Briefly, the essential clinical features are diffuse, deeply pigmented, soft, verrucous papules and plaques, symmetrically located, particularly in the body folds such as the axillae, infra-mammary, genito-crural and perianal regions. Sometimes the neck, ante-cubitals, popliteals and even the mucous membranes may be involved. It is important to distinguish this from a benign type of the disorder which is clinically and pathologically similar, but usually appears at birth or in early childhood, reaches its peak at puberty, and then either regresses or remains stationary. This type has also been called the juvenile variety and is not associated with any form of cancer. According to Curth,[9] the incidence of herpes zoster in patients having carcinoma of the stomach, breast, uterus and ovaries is about twice as great as in the general population. This eruption is almost always a late manifestation and is frequently indicative of metastases. Erythematosquamous, exfoliative dermatitis and bullous eruptions have all been observed in association with internal cancer. Spider nevi of the face and trunk have been noted in primary or metastatic liver cancer; however purpuric and hemorrhagic eruptions are apparently rare. The association of dermatomyositis with internal carcinoma has been noted with increasing frequency. About 20 per cent have an associated carcinoma either in the breast, ovary, lung, stomach, gall bladder or kidney.[10] In some, dermatomyositis preceded the cancer and in others the reverse was true. Curtis[11] reported that improvement of the dermatomyositis occurred in six out of eight patients following treatment of the malignancy.

The malignant lymphomas represent a group of neoplastic disorders characterized by the proliferation of cells of the lymphoid and reticulo-endothelial systems and may occur in any body organ, including the skin. Unfortunately, since there is no clear-cut differentiation between these various processes, a great diversity of opinion exists as to their proper classification. However, this paper shall include only those which may be found in the skin, sometimes occurring there before appearing in other body organs. The incidence of cutaneous signs and symptoms in diseases of this group varies in different series. However, the usually accepted average for the entire group is about 40 per cent.[12] Non-specific changes are more common than specific ones.

The incidence of cutaneous symptoms and signs occurring in Hodgkin's disease as reported by several authors, varies from 25 to 50 per cent. In about 10 per cent, these manifestations represent the initial presenting complaint of the patient. Persistent, severe pruritus, sometimes generalized, but often confined to the lower extremities including the soles of the feet, is the most common cutaneous symptom of Hodgkin's disease. Excoriated papular and urticarial lesions, hyperpigmentation, dryness and thickening of the skin are also frequently seen. Exfoliative erythroderma is a fairly common manifestation and sometimes may be the initial symptom. According to Montgomery,[13] herpes zoster occurs more frequently in Hodgkin's disease than in any other type of lymphoma. The lesions of this eruption often disseminate, become generalized, and may contain a specific infiltrate. Specific lesions, such as nodules and infiltrated plaques, rarely occur but, when they do, have a tendency to ulcerate.

Cutaneous involvement occurs in about 25 per cent of all types of lymphosarcoma.[14] Primary cutaneous lesions are rare and metastatic nodules constitute the most frequent finding, accounting for approximately 90 per cent of the specific type

of lesions. They are usually firm, indolent nodules varying in color from red to brown and frequently undergo ulceration. Generalized pruritus, exfoliative dermatitis, herpes zoster and a variety of nondescript cutaneous reactions have also been observed in patients having lymphosarcoma.

Cutaneous lesions are seen in about 40 per cent of patients having the various types of leukemia.[15] Morphologically, the lesions are similar regardless of the variety and type of leukemia. In the acute forms, the lesions tend to be purpuric and hemorrhagic and are often associated with oral ulcerations. Papulo-pustular and pyodermic eruptions are also frequently seen. In the chronic types, specific lesions are more common in lymphatic than myelogenous and in some cases may appear before other evidences of the disease. In most instances, they are metastatic, although sometimes they may be primary in the skin. Clinically, the lesions vary in size from a few millimeters to several centimeters. They are usually firm, discrete and vary from red to bluish-brown in color. In lymphatic leukemia, they have a predilection for the face and the hands, although they may be found on other areas of the body. Ulceration of the lesions often occurs. Sometimes the facial infiltrations are diffuse, producing a leonine appearance. Another, less frequent, cutaneous manifestation is generalized exfoliative erythroderma which, in rare instances, may even be the initial symptom of the disease. Although Beek[16] reported this reaction occurring in 25 per cent of the patients with lymphatic leukemia, most observers have not experienced this high an incidence. Herpes zoster, often generalized, is sometimes seen. The lesions may or may not show specific leukemic infiltrations. In myelogenous leukemia specific tumors are less common. They have a predilection for the trunk and extensor surfaces of the extremities and rarely ulcerate. Prurigo-like maculo-papular lesions, hemorrhagic changes, urticarial and bullous eruptions are some of the non-specific changes which have been observed in the leukemias and severe generalized pruritis may be a prodromal symptom.

Mycosis fungoides is a chronic progressive disease which primarily involves the skin, although other internal organs may be affected. It usually starts with intense generalized pruritus, followed by erythematous and eczematous patches or even generalized exfoliative dermatitis. After a variable period of a few months to several years, the skin lesions become thickened and infiltrated. In the final stage several bluish-red brown tumors develop. These have a tendency to break down and ulcerate. Positive microscopic identification of the disease can only be made in the infiltrative or tumor stages.

Summary

1. A review of the cutaneous manifestations associated with some internal cancers and malignant lymphomas is presented.

2. Both specific and non-specific lesions may occur.

3. The non-specific changes are more common and consist of a variety of localized or generalized primary and secondary skin lesions.

4. The specific types are composed of nodules and infiltrative plaques of tumor tissue.

*Type 1 poliovirus isolated

POLIOMYELITIS EPIDEMIC on a

THIS REPORT concerns an epidemic of Type I poliomyelitis occurring on a northern Minnesota Indian Reservation. Fourteen confirmed cases of poliomyelitis were diagnosed among the 460 Chippewa residents of the 168 square mile Bois Fort Reservation during August and September, 1959. In five other individuals, polio was strongly suspected but unconfirmed. Type I polio virus was also cultured from the stools of nine other individuals not evidently ill, four in case contacts and five scattered in the community which were also contacts. The epidemiologic survey was performed by a team from the State Department of Health: actual care of the patients was given in several surrounding hospitals.

It was reasoned that this outbreak represented an interesting rural prototype of recent outbreaks (generally urban). It involved: (1) an essentially non-caucasian population, (2) low socio-economic standards, (3) large family size, (4) crowded living conditions, (5) low standards of hygiene, and (6) a low incidence of Salk vaccine coverage.

The people of Bois Fort Reservation, located 300 miles north of Minneapolis-Saint Paul, are

R. A. MACDONALD, M.D.
Littlefork, Minnesota

Minnesota Indian Reservation

isolated by geography as well as social and economic factors. Most of the people live in Nett Lake, a village set in the deep forest of northern Minnesota. The rate of indigence is high. Large families are the rule, and many of the homes are very crowded. Community and personal hygiene are comparatively low. The population is strikingly younger than state average—60.4 per cent are younger than twenty years of age as compared to 35.6 per cent for the whole state. The low Salk vaccine immunization rate is emphasized in Table 2.

A comparison of these vaccination rates with those of Minnesota in general within certain age groups is shown below and illustrates how poorly the reservation was actually covered.

Table 3
Comparison of Salk Vaccination Rates,
Minnesota versus Nett Lake

Age	Any Vaccine		3 or more doses	
	Minnesota	Nett Lake	Minnesota	Nett Lake
0 — 4	82%	34.0%	41%	5.4%
5 — 9	95%	36.5%	50%	14.2%
10 — 14	95%	45.5%	33%	18.2%
15 — 19	86%	41.7%	20%	13.9%

On August 18, 1959, six days after the first case was recognized, and on October 1, 1959, immunization clinics were held at Nett Lake. One hundred and thirty immunizations were given at

the first clinic: 127 to children under twelve, and three to expectant mothers. Seventy-five to 100 individuals over this age group had to be turned away for lack of vaccine which was very scarce at that time. Below is a table showing distribution of the 130 shots given.

106	received the first dose
12	received the second dose
8	received the third dose
4	received the fourth dose
130	— total

(These doses are not included in the figures shown in the above tables.)

At the second clinic 166 shots were given and below is the table showing distribution of these shots.

55	received the first dose
81	received the second dose
13	received the third dose
17	received the fourth dose
166	— total

It is known that a fairly large number of people received shots in the offices of private physicians during this time.

This outbreak is of interest in that the various characteristics seen in recent epidemics are all present, but in an isolated area—rural—rather than the underprivileged sections of a city. It is obvious that a large percentage of the population was infested with the virus, whether ill or not. Of interest is the fact that four of the ten paralytic cases showed paralysis of the seventh cranial nerve, with this being the only paralysis in three of these four cases. All but one of the cases were in children six years old or younger. None of the cases showed any respiratory paralysis and there were no deaths. Two of the paralytic cases had each received two shots of Salk vaccine; two of the non-paralytic and abortive cases had received one shot each. The Nett Lake population in general was very poorly protected. A conclusion one is forced to make is that prior immunization might have controlled this outbreak. Nett Lake has missed out completely on the school immunization "clinics" which are common practice in other communities of the area. This is due in part to its isolation, low economic level, and to the lack of any organized public health authority presently responsible for such a project. The vacancy created by the recent policy changes whereby Bureau of Indian Affairs discontinued giving reservation Indians free medical care was not filled by the county health authorities of the two counties in which Bois Fort Reservation lies. Initiative for obtaining the Salk vaccine fell on the Nett Lakers themselves.

Several years of close and friendly contact with the Nett Lake people, as the contract physician, from 1950 through 1954, showed me that these people needed little urging to avail themselves of such medical necessities as immunizations. During my years of holding once-a-week office hours on the reservation, I found that virtually all of the youngsters were brought in for the then-available shots.

My final conclusion is more sociologic than medical. Because it seems clear that adequate immunization would have prevented this outbreak, I feel that our profession must assume the responsibility for seeing that the vaccine and the whole public are brought together. I do not believe that it is necessary that governmental agencies provide this service. If we private physicians will cheerfully and willingly step into the breech and provide immunizations for a nominal charge at mass clinics, I believe we can strike a real blow for the health of our country and for ourselves too, in less government regulation and more public good will. Over the years I have held many immunization clinics (for adults and children alike) in the rural villages of our area, and have found an overwhelming acceptance by the people and a much higher rate of immunization than otherwise possible.

Summary

This discussion has centered about fourteen cases of polio Type I occuring on a small Indian reservation in Northern Minnesota, tracing out the striking resemblance to the recent urban outbreaks. I have suggested that the epidemic probably might have been prevented with prior adequate immunization, and have concluded with an urgent plea to my colleagues to participate freely in immunization "clinics" for adults and children alike—and especially in the underprivileged areas where the need is the greatest.

Report of Case

Relapses of Porphyria induced by Chloroquine (Aralen) Phosphate

WARREN L. MACAULAY, M.D.
Fargo, North Dakota

FOLLOWING Page's 1951 rediscovery of quinacrine (Atabrine) hydrochloride's effectiveness in chronic discoid lupus erythematosus,[1] wide use was made of this drug for that disorder. Understandably, the light sensitivities were soon included. Atabrine was eventually replaced by chloroquine (Aralen) phosphate,[2] another antimalarial, which, aside from being less toxic, had the added advantage of not producing the objectionable yellowing of the skin so characteristic of Atabrine ingestion. Clinicians soon began to employ chloroquine empirically for a variety of conditions. A recent review of the literature has disclosed reports on the use of this drug in such divergent disorders as malaria, all forms of lupus erythematosus, light sensitivity, rheumatoid arthritis, amebiasis, tape worm infestation, scleroderma, creeping eruption, neurodermatitis, vitiligo, pemphigus, rosacea, porphyria, acrodermatitis chronica atrophicans, lichen planus, verrucae, granuloma annulare, and recalcitrant vesiculo-pustular eruption of the palms and soles. It is obvious that this drug, alone or combined with other antimalarials (Triquin), is being used extensively for various specific and nonspecific "antiphlogistic" effects.

The incidence of side effects from chloroquine is moderate.[3] Toxic manifestations, however, are usually not of a serious nature and are ordinarily corrected by discontinuing the drug. The more commonly reported ill effects include pruritus, nausea, anorexia, diarrhea, headache, difficulty in visual accommodation—apparently due to corneal epithelial changes, weight loss, and depigmentation of the scalp hair. Less frequent ill-effects include electrocardiographic changes characterized by T-wave depression, leukopenia, lymphedema of forearms and hands, methemoglobinemia, lichenoid dermatitis, exfoliative dermatitis, alopecia, and abnormal pigmentation. Pre-existing psoriasis may be precipitated into an exfoliative erythroderma by this drug.

Porphyria occurring during chloroquine therapy has been reported in three previous papers.[4-6] The scarcity of such reports indicates that this is an unusual and infrequent complication. However, in view of the current widespread use of this drug, clinicians should be advised of this phenomenon.

Report of Case

A forty-five-year-old carpenter, employed at a slaughter house, was first seen in August 1954 with a facial eruption of six years' duration. Dark red, indurated, scaly plaques with some atrophy and associated hypo- and hyperpigmentation were present anterior to and below each ear. Clinically, the eruption appeared to be chronic discoid lupus erythematosus. A biopsy done at this time was reported as showing the classical features of chronic discoid lupus erythematosus. Coincidentally the patient complained of an eruption on the dorsum of the right hand of two and one-half months' duration. This appeared to be simple pyoderma. Blisters reportedly developed on the hand as a result of spark burns from a welding torch. However, in view of his subsequent history, these lesions may have been a manifestation of porphyria cutanea tarda. The patient was given Atabrine which he took somewhat irregularly. Within one month the lesions were less infiltrated, but improvement was not marked.

The patient was not seen again until he was admitted to the medical service of Dr. A. C. Fortney in May 1956. Three weeks prior to admission he developed anorexia and vomiting. These complaints persisted until several days prior to admission when he developed chills and profuse sweating. He reported that his urine seemed dark while his stools were of normal color. The patient appeared toxic but physical findings, except for the chronic discoid lupus erythematosus of the face, were essentially normal. The Watson test[7] revealed the presence of excessive porphyrins in the urine, the final extracts glowing with bright red fluorescence under the

From the Department of Dermatology, Fargo Clinic, Fargo, North Dakota.

Wood's lamp. Unfortunately, facilities for quantitative porphyrin determinations were not available. To complicate the problem, hemolytic staphylococci were reported in blood cultures, and the Brucella agglutinin titre was reported as 4+ at 1:1200, 1+ at 1:1600 and negative at 1:3200. One week later these titres were reported as 3+ at 1:1600 and 1+ at 1:3200. This incredible combination of illnesses, associated with an irregular febrile course and with a normal leukocyte count, finally yielded to supportive therapy, erythromycin, aureomycin, and chloromycetin. During this admission it was learned that the patient drank beer every day.

On August 13, 1956, apparently feeling well and with no clinical signs of his recent acute illnesses, this patient returned to the Dermatology Department stating that the plaques of discoid lupus erythematosus on the face were being irritated by the summer sun. A sun-shielding cream was prescribed, and the patient started on chloroquine in dosage of 250 mg. twice daily.

Five days later (August 18, 1956), the patient was admitted to the medical service of Dr. A. C. Fortney complaining of extreme weakness, hematemesis, left-chest pain, and nonproductive cough. He was listless and lethargic. These symptoms had appeared three days prior to admission or two days after initiating chloroquine therapy. The patient stated that he was unable to "catch his breath" since starting chloroquine. His temperature was 102° F. on admission. At this time the Watson test again was positive for excessive urinary porphyrins. A chest x-ray was negative. The leukocyte count was 8,200. This attack subsided uneventfully, and the patient was discharged from the hospital after a five-day stay.

On February 10, 1957, the patient was admitted to the hospital on the medical service of Dr. P. O. Triggs. At this time he complained of pain in the left chest, chilly sensations, sore throat, and dark red urine. He was very irritable. Moist râles were detected at the right lung base posteriorly. A roentgenogram of the thorax revealed pneumonitis in the medial aspect of the right lower lobe. Throat culture revealed alpha streptococci. Again the Watson test for urinary porphyrins was reported as positive. Admission temperature was 103° F. The leukocyte count was 17,400. The patient responded rapidly to a combination of novobiocin and penicillin and was discharged after a six-day hospital stay.

On May 18, 1958 the patient was admitted to the medical service of Dr. P. O. Triggs with a complaint of chills, sore throat and right sided chest pain of two days' duration. His temperature was normal at the time of admission and remained so during a seven-day hospital stay. The Watson test on May 20, 1958 was again reported as positive. A thoracic roentgenogram revealed a small zone of fibrosis at the right lung base, representing possibly a residual of the previous pneumonia or current pneumonitis. The leukocyte count was 10,150. Within four hours after receiving penicillin intramuscularly, an allergic reaction developed consisting of generalized urticaria and severe pruritus. Penicillinase (Neutrapen) was given intramuscularly, and the eruption disappeared within two days. At the time of this admission it was noted that the eruption on the face remained unchanged. Since the patient had not had any specific therapy for his facial eruption in recent years, it was decided at the time of discharge (May 24, 1958) to restart chloroquine at a dosage of 250 mg. daily.

Within five days (on May 29, 1958) the patient was re-admitted to the hospital with complaints of weakness, vomiting, and dark red urine of two days' duration. The laboratory again reported excessive porphyrins in the urine. The leukocyte count was 5,700. The patient followed an afebrile course and was discharged after seven days.

On October 12, 1959, the patient was admitted to the hospital in an intoxicated condition with a complaint of lower back pain. It was not determined whether he had fallen and hurt his back or whether he had suffered back strain as a result of lifting. He had been drinking rather heavily recently. His urine has been red intermittently since his last admission.

Discussion

This patient was hospitalized on six occasions over a three and one-half year period. On each admission, a diagnosis of porphyria alone or associated with other illness was made. Two of these relapses of porphyria occurred within two to three days after starting chloroquine therapy for chronic discoid lupus erythematosus. While admittedly an instance of labile porphyria, attacks being precipitated by a variety of illnesses and probably by alcohol, it was difficult to escape the conclusion that chloroquine was the precipitating agent in these two relapses. The patient supported this clinical impression by independently announcing his refusal to take this medication again, exclaiming, "those pills throw me for a loop."

Summary

A case of porphyria is reported in which chloroquine (Aralen) phosphate was incriminated as precipitating several relapses of the disease.

CORONARY ANATOMY

for the Practicing Internist

THOMAS N. JAMES, M.D.
Detroit, Michigan

THE BASIC SCIENCES of medicine are the foundation of clinical practice. Tempered with careful observation, the wisdom of experience, and the art of dealing with human beings as patients, the basic sciences become applied knowledge and as such perpetually more fascinating. Without them, the art of practice relentlessly regresses to opinionation not based on fact, and ultimately to chicanery.

Cardiology, long one of the major fields of internal medicine, has been made increasingly important by the development of newer and more successful methods of therapy, but also by the rising incidence of coronary disease, for which present therapy leaves much to be desired. One of the basic sciences capable of contributing much to our understanding, and thereby improved treatment, of diseases of the heart is anatomy. To illustrate this point, some observations on the anatomy of the coronary arteries, the crown of the heart, are herewith presented.

If knowledge of the exact location of a coronary occlusion is not important, then an enormous amount of present effort for the production of roentgenograms of the coronary arteries is being misdirected. It is of course important, but not all the reasons are fully appreciated.

An acute coronary occlusion is not, like Gertrude Stein's rose, just an acute coronary occlusion. It behaves differently depending on where the sub-

Portions of this material were presented at Postgraduate Course No. 6 of the American College of Physicians, held at Henry Ford Hospital, January 25 to 29, 1960.

sequent myocardial infarction occurs. Consideration of just a few simple points of human coronary anatomy can help explain this difference in behavior. Although many myocardial infarctions (perhaps the majority) are streaky or lamellar or diffuse,[1] enough of them involve specific localized areas to warrant their consideration.

Of these discrete infarcts, there are three groups, each of which is due to occlusion of one of the three main coronary arteries:

1. Anteroseptal infarcts are due to occlusion of the left anterior descending coronary artery.

2. High lateral infarcts are usually due to occlusion of the left circumflex artery.

3. Posterior infarcts are due to right coronary artery occlusion.

Mixed infarcts are better understood if the three basic infarcts above are remembered.

1. *Anteroseptal infarcts* are the commonest of these three. The primary electrocardiographic changes are in leads I, aVL, and V2 to V4. Other factors being equal, more proximal occlusions of the left anterior descending artery produce larger infarcts. Blood supply via anastomoses comes from three directions[2,3]: (1) through the interventricular septum and around the apex from the posterior descending coronary artery, (2) across the free wall of the left ventricle from the left circumflex artery, (3) across the free wall of the right ventricle from the right coronary artery. These same collateral routes apply conversely in occlusion of the other two main coronary arteries. Although the perfusion pressure delivered to the coronary arteries is the major physiologic determinant of flow through coronary anastomoses,[4] patency of the main coronary arteries obviously helps determine this.

For practical purposes, myocardial infarction is left ventricular infarction, the septum being considered part of the left ventricle. Since the left anterior descending artery supplies more of this area, its occlusion produces larger infarcts. As far as the loss of ventricular mass contributes to it, congestive failure is thus more often a problem of anteroseptal infarction. For the same reason, ventricular aneurysm and cardiac rupture following the occlusion of a single artery are more to be anticipated following left anterior descending artery occlusion. Aneurysm, rupture, and congestive failure are all commoner with occlusion of two or more arteries, however.

Ventricular arrhythmias are as apt to occur with left anterior descending artery occlusion as with left circumflex occlusion; as a consequence of heart block they are commoner with posterior infarcts, as will be discussed later. Supraventricular arrhythmias and AV block are rare with isolated occlusion of the left anterior descending artery, since it virtually never supplies the SA or AV nodes or upper conduction system.

Sudden occlusion of the main left coronary artery is seldom a therapeutic clinical problem, most patients failing to survive its abrupt closure. Isolated reports of survival after main left coronary occlusion—or even complete occlusion of both right and left main coronary arteries—are cases of gradual occlusion with remarkable development of collateral circulation.

2. *Lateral infarcts* involve the obtuse margin of the left ventricle, usually more toward the base than apex of the heart. Electrocardiographically the primary changes are in leads I, aVL, and HV3 to HV5 (high leads); the conventional precordial V leads are conspicuously normal or show only the edge of the infarct. These infarcts in 90 per cent of cases are due to occlusion of the left circumflex coronary artery. The point of occlusion is most likely to be in the proximal third of the artery, for occlusion more distally (the other arteries being patent) can be compensated for with high efficiency by collateral flow.

Blood supply of the human SA node comes from the left coronary in about 45 per cent of cases and from the right coronary artery in the remaining 55 per cent; it is virtually always unilaterally derived.[5] In its origin from the left the sinus node artery arises within one centimeter proximal or distal to the bifurcation of the main left coronary artery; the distal origin is always from the left circumflex, not the left anterior descending artery. If the origin is proximal to the bifurcation, which is uncommon, an occlusion of the main artery proximal to it is seldom a problem in clinical management, since it is usually immediately fatal.

Occlusion of the left circumflex artery proximal to the origin of the sinus node artery usually is associated with atrial fibrillation,[6] which is of great localizing value. Thus if atrial fibrillation occurs during an acute lateral myocardial infarction, the point of occlusion is almost certainly in the first centimeter of the left circumflex artery. Prognostically this is grave, for any proximal propaga-

tion of the thrombus may occlude the main left coronary artery. It was empirically observed long ago that atrial fibrillation was a grave prognostic sign in lateral infarcts,[7] though the explanation was unsatisfactory.

3. *Posterior infarcts* are the most interesting from the standpoint of coronary anatomy. Since 90 per cent of humans supply the crux of the heart (where most "pure" posterior infarcts occur) via the right coronary artery, it follows that 90 per cent of these infarcts will be due to right coronary occlusion. Primary electrocardiographic changes occur in leads III, aVF and V8. A prediction with 90 per cent accuracy is about as good as the Wassermann test. It makes one hesitate about coronary arteriography in these particular cases.

One can even improve on the 90 per cent accuracy, however. Ten per cent of humans (15 per cent of men and 5 per cent of women) supply the crux of the heart via the left circumflex artery. If posterior infarction in these cases is due to occlusion of the left circumflex artery, it is usually associated with lateral infarction and there will be primary electrocardiographic changes not only in III, aVF and V8, but also in HV3 to HV6, aVL and V6. Occlusion of the distal left circumflex artery in this 10 per cent variation is unlikely to produce infarction, for collaterals from the right coronary and proximal two-thirds of the left circumflex can be very efficient.

Posterior infarction of the heart involves the primary blood supply of the AV node, for the AV node artery arises from the main coronary artery that crosses the crux.[2,3] This is the reason AV block and Stokes-Adams seizures are associated most commonly with posterior infarcts.[8,9] Syncope at one time or another is a common feature of the history of patients with posterior infarcts, and the onset of the infarction itself may be marked by loss of consciousness or even a convulsion. With frequent recording of electrocardiograms some degree of AV block can be detected in the majority of posterior infarcts, although this may not appear until the third or fifth post-infarction day.[6]

Because AV conduction in posterior infarcts may be expected to be impaired, drugs which depress cardiac conduction (such as quinidine) should be used with appropriate caution. Similarly, in the management of patients with posterior infarcts it is well being forewarned to be forearmed with means of coping with sudden complete heart block. An unexplained manifestation of some acute posterior infarcts is an intense sinus bradycardia.[6] It is my impression that this is a manifestation of intense vagotonia, and that vomiting, diaphoresis, tenesmus, and even sialorrhea are commonly encountered in patients with posterior infarcts. Why vagotonia should be commoner with posterior infarcts is conjectural.

Not only can one presume occlusion of the right coronary artery in posterior infarction with better than 90 per cent accuracy provided there is no lateral infarction present, just as in lateral infarcts the onset of atrial fibrillation is of additional localizing value. It will be recalled that the sinus node artery arises from the right coronary artery in about 55 per cent of humans. The point of origin is virtually always from the first two to three centimeters. Thus if a patient with a posterior infarct develops atrial fibrillation, not only can you be quite certain the right coronary artery is the one occluded, you can also know the occlusion is proximal to the sinus node artery which must arise from that side. The exact point of occlusion can thus be localized in the first two centimeters of the right coronary artery.

Admittedly this oversimplifies the anatomy of coronary occlusion, for more often than not, more than one artery is involved. An understanding of the anatomy of simple coronary occlusion, however, not only assists in planning clinical therapy and prognosis of these particular patients, but also will lead us to a more rational study and final unraveling of the more complex cases.

Medicine and its Practitioners in Mower County Prior to 1900

NORA H. GUTHREY
Stewartville, Minnesota

Lyman Drake Jackson (1851-1892), eldest son of Deacon L. A. Jackson and Emily Drake Jackson, was born on January 31, 1851, in Milton, Chittenden County, Vermont. He received his early education in the schools of Milton and at the Lamoille County Grammar School, in Johnson, Vermont. From childhood, he planned to be a physician, but circumstances prevented his study of medicine until, at the age of twenty-two years, he came west to Lime Springs, Iowa. There he was employed in, or operated, a drugstore and read medicine with Dr. John W. Reed, formerly of Alburgh, Vermont. In 1877 Dr. Jackson was graduated from Rush Medical College, Chicago. In that year he began the practice of medicine in Dexter, Mower County, and in 1879 settled in Grand Meadow, where he was in active practice for thirteen years, until shortly before his death, at the age of forty-one.

In 1880, Dr. Jackson was married to Cornelia D. Paddock, of Grand Meadow, a native of Alabama. Dr. and Mrs. Jackson had one child, Edith E., born in Grand Meadow in 1881. They were members of the Congregational Church.

Dr. Jackson was admitted to membership in the Minnesota State Medical Society in 1880. In that year also he was an organizer of the Southern Minnesota Medical Society, the first medical group to be organized in Mower County. Under the "Diploma Law" of 1883 he received certificate No. 148 (R), dated October 13, 1883. In the early eighties he helped to organize a board of health in Grand Meadow, and he served from time to time as a county physician. He has been remembered as "a radical Republican," and as a member of the local Masonic Lodge.

On October 22, 1892 (year indicated in the *Transactions* of the state medical society), Dr. Jackson died, in Grand Meadow, from paralysis with which he had been stricken twelve days earlier. He was survived by his wife, his daughter, his father, who was visiting in Grand Meadow at the time, and by other members of the family in the East. Burial was in the family lot in the beautiful cemetery at Milton, Vermont.

At the time of his death, it was written of Dr. Jackson in a newspaper of Mower County, "The doctor has been a tireless worker and a good physician, being known as such throughout the entire country near here."

Samuel M. Jenks, said by some compilers of early history in Mower County to have been a native of New York, was a graduate of Rush Medical College who came to Grand Meadow in 1872, the year of his graduation, the first physician in the village. He was "a well-educated, successful physician." In the Andreas illustrated atlas of Minnesota, of 1874, there is the following entry: "Grand Meadow Township. Samuel M. Jenks, physician and surgeon. Born in Sandusy City, Ohio, came to Minnesota in 1868. Post Office Grand Meadow." For a year or two in 1876-1878 Dr. Jenks took a Dr. Wilder (*q.v.*) into partnership, in practice and in his drugstore.

In 1880, Dr. Jenks removed to Madison, Lake County, Dakota Territory, from which place he duly was registered as a physician (R) under the Dakota medical practice law of 1885. It is said that he died there about 1925.

Charles Harcourt Johnson (1859-1917) practiced medicine in Austin thirty-three years, from 1884 until his death.

Born on January 15, 1859, at a farm home near Farmersville, Leeds County, Ontario, Canada, he was the son of Mr. and Mrs. Samuel Johnson. He studied at the Almonte Collegiate Institute, Almonte, Ontario, and in March, 1884, was graduated in medicine from McGill University, Montreal. In June of that year he began the practice of medicine in Austin, Minnesota. For a time he was in partnership with Dr. Alexander MacDonald (1856-1947), a graduate of McGill in 1883, who had arrived in Austin in that year. Dr. Johnson was licensed in Minnesota on August 18, 1884, receiving certificate No. 939 (R).

Dr. C. H. Johnson was a brother of Dr. J. Ross Johnson (1855-1905), a graduate of McGill University in 1883, who from that year until his death practiced in Spring Valley, Fillmore County; and a half brother of Dr. William Nassau Kendrick (1872-1936), a graduate of McGill in 1896, who practiced with Dr. J. Ross Johnson in Spring Valley from 1896 to 1898, and from the latter year to 1905 with Dr. C. H. Johnson in Austin. In 1905 Dr. Kendrick returned to Spring Valley.

In Austin, Dr. Charles H. Johnson served six terms as mayor of the city, during which he brought about many improvements, including a sewer system, electric lighting, a viaduct, new fire-fighting apparatus, and extension of public utilities. He was several times a county physician, was an examiner for the United States Bureau of Pensions, and was surgeon for the Chicago, Milwaukee and St. Paul Railway Company. He was an early member of the Mower County Medical Society and automatically a member of the Minnesota State Medical Association.

Dr. Johnson was a member of the Episcopal Church, a Democrat, a member of various fraternal organizations, among them the Masonic Lodge, Modern Woodmen of America, Ancient Order of United Workmen, Knights of Pythias, Order of Eagles and Order of Owls. He is remembered as a genial man, well liked, liberal and charitable, a faithful civic servant, and an ethical and skillful physician.

A nephew of Dr. Johnson was the late Dr. Charles Harcourt Johnson of Spring Valley, son of Dr. J. Ross Johnson.

Frank M. Johnson was in southern Minnesota as a general practitioner of medicine and surgery from 1883 into 1896, for seven years in Mower County.

Born at Fort Atkinson, Jefferson County, Wisconsin, on August 29, 1854, Frank M. Johnson when a child removed with his parents to Vernon County, Wisconsin, and there grew up. He attended the high school at Viroqua, took an academic course at Wayland Academy in 1876, and in the three years immediately following studied medicine with Dr. William Gott of Viroqua. Soon afterward he enrolled at Rush Medical College, from which he was graduated in 1882. The scene of his first practice, for a year and a half, was Ontario, Vernon County, Wisconsin. He was married there to Ida De Lapp, a native of the village, born on December 2, 1860.

In September, 1883, Dr. and Mrs. Johnson and their infant son, Lee F. Johnson, settled in Brownsdale, Mower County, Minnesota. Dr. Johnson was licensed in the state on December 31, 1883, receiving certificate No. 958 (R); he was listed as living in Grand Meadow. It appears, however, that he remained in Brownsdale for two or three years before removing to Grand Meadow; in Grand Meadow he practiced medicine and ran a drugstore until January, 1890, when he went to Byron, Olmsted County. Dr. Johnson was a Baptist and a Prohibitionist; in 1890, in Olmsted County, he was nominated as coroner by the Prohibition Party.

Early in 1892, Dr. Johnson went with his family from Byron to Dover; in this period he took a graduate course in medicine in Chicago. He early became a member of the Southern Minnesota Medical Association (1892). In May, 1896, Dr. and Mrs. Johnson and their three children removed to Springfield, Missouri, where they remained until 1931 (according to the AMA directory).

L. D. Johnson has been mentioned as having been in Dexter, and in Grand Meadow, in 1884. Information about him has not been available. It seems probable that the name may have been confused with that of Dr. L. D. Jackson.

J. C. Jones, believed to have been the first physician to practice medicine in Mower County, in the spring of 1855 came to Le Roy Township accompanied by his wife, and "settled on the Joe Mason farm." Dr. Jones and his wife were both practitioners of the Thomsonian school. They followed their profession in the

locality of Le Roy until Dr. G. M. Allsdurff came to the village in 1864, after which they are said to have retired from practice. In 1868 they went to Missouri to engage in farming, an occupation in which they were continuing in 1884.

W. C. Jones came to Austin in 1862 and engaged in a limited practice. On his professional card he announced that he had had thirty years' experience in the practice of medicine and surgery. He died in Austin about 1879.

More is known about B. F. Jones, son of Dr. W. C. Jones, than about the father. In 1860, B. F. Jones began publication in Austin of the *Minnesota Courier;* he was assisted in the enterprise by the directors of what was then the McGregor and Mankato Railroad Company (later the Iowa division of the Chicago, Milwaukee and St. Paul Railway Company). The purpose of the newspaper was to attract settlers to Austin and thus make the city a central point. In January, 1861, Mr. Jones entered the Union Army. Further record does not appear until August 26, 1874, when the first issue of the *Independent,* of Austin, was printed, with B. F. Jones as editor.

L. Joslin, according to notes by Armstrong, "located in Austin in 1898 and was at that time the only physician in town who owned an ophthalmometer." Dr. Lester Joslin, a graduate of the Medical Department of Western Reserve University in 1867, was listed from 1886 to 1900, inclusive, as in Ionia, Michigan. He may have been briefly in Austin, Minnesota.

Emma Adeline Keeney opened an office in Austin probably in 1898. Born in 1876, she was graduated in 1897 from the College of Homoeopathic Medicine and Surgery of the University of Minnesota. In April, 1898, she was licensed to practice in Minnesota. There is evidence that she began her professional career in Spring Valley, Fillmore County, and practiced there for possibly a year; in a business directory of 1898-1899 listed the name of "Mrs. E. A. Keeney" as a physician.

From Spring Valley Dr. Keeney moved to Austin, where for a time she was in partnership with Dr. Fannie G. Kimball Fiester. After a few years Dr. Keeney took graduate work, and in 1904 was graduated from the Hering Medical College of Chicago. Presumably she settled soon afterward in Albert Lea, Freeborn County, where she was practicing in 1907. In 1909 she was licensed to practice in the state of Oregon, and into 1914, after which record did not appear, she was in active practice in The Dalles, Oregon.

William Nassau Kendrick was born at Athens, Leeds County, Ontario, Canada, the son of Samuel Kendrick and Amelia McNish Kendrick, both of English parentage and natives of Oak Leaf, Ontario.

William N. Kendrick went to school in Athens, and subsequently was a student at the Almonte Collegiate Institute, at Almonte, Canada, from which he was graduated with honors in 1890, at the age of seventeen. Two years later, having decided to become a physician (like his half brothers, who were then in Minnesota: Dr. J. Ross Johnson, Spring Valley, and Dr. Charles Harcourt Johnson, Austin), he entered McGill University, from which he was graduated in medicine in 1896, again an honor student and the president of his class, with the degrees of M.D. and C.M.; among the awards for scholarship which he had received during his course of four years were the Primary Prize, the Prize for General Proficiency, and the Gold Medal for Proficiency in Chemistry.

Immediately after graduation, Dr. Kendrick came to Spring Valley, Fillmore County, to join Dr. J. Ross Johnson in practice. On June 9, 1896, he was licensed as a physician in Minnesota. In Spring Valley, on October 14, 1896, he was married to Maude M. Lloyd, daughter of Mr. and Mrs. L. M. Lloyd of that place.

In 1898 Dr. Kendrick joined Dr. Charles H. Johnson, who was in ill health, in practice in Austin, where he remained eight years. During these years there were born to Dr. and Mrs. Kendrick two children, Dorothy Gertrude and William Lloyd.

In 1905, after the death of Dr. J. Ross Johnson, Dr. Kendrick returned with his family to Spring Valley, where he spent the remaining thirty-one years of his life, a loved physician, high in the esteem and confidence of his patients and fellow townsmen. (See sketch of Dr. Kendrick in medical history of Fillmore County.)

— **Kimball,** mentioned as being in Austin, Mower County, in the nineties, was Dr. Fannie Gray Kimball (Fiester).

E. J. Kingsbury, who became a well-known citizen and medical practitioner of medicine in southern Minnesota, was a native of New York, born in Franklin County August 23, 1832. When he was four years old, the family moved to St. Lawrence County, New York, where he grew up. He obtained his preliminary and academic education at the district school in Potsdam, at a select school in Raymondville, and during six years at the Raymondville Academy under Professor Montague. Thus prepared, at the age of eighteen he began to study medicine under preceptors —the first, Dr. Herman A. Boland, of Raymondville, and the second, Dr. Goodrich, of Potsdam. He completed his medical training by attending lectures at the American Medical Institute at Cincinnati, from which institution he was graduated on March 14, 1854. Beginning his medical practice in Oswego County, New York, he remained there until the autumn of 1855, when he came to Minnesota Territory and settled in Mower County. Here, he pre-empted the southwest quarter section 20, town 102, range 14, in the present Bennington Township, and in due time assisted in the organization of the township and served as first chairman of the first board of supervisors. He may have practiced medicine at this time. After a few years he removed, in the autumn of 1860, to Spring Valley, Fillmore County, where he was in active medical practice for eight years. During this period, the county records occasionally mentioned his receiving fees for medical attendance on paupers.

In Spring Valley, he was for a time in partnership with his brother, Dr. W. B. Kingsbury (about whom no other information has appeared) in the practice of medicine and surgery, and further, as set forth in a professional card:

> E. J. Kingsbury, having been appointed Examining Pension Surgeon by the Commissioner of Pensions, will attend to all applications for pensions with promptness and dispatch. They will also attend to the collection of back pay and Bounty.
>
> E. J. Kingsbury
> W. B. Kingsbury

Late in 1868, Dr. E. J. Kingsbury went to Decorah, Iowa, where he remained until 1870, when he again settled in Mower County, in Le Roy, which became his permanent home. His arrival in Le Roy coincided with an outbreak of diphtheria during which he served faithfully, winning the confidence of the community.

E. J. Kingsbury was married twice, the first time on July 3, 1853, to Lucia A. Angell, who was born at Pomfret, Vermont, on April 8, 1829. Mrs. Kingsbury died in Spring Valley on September 28, 1867, leaving one child, Flora A.; an infant son had died a year earlier. Dr. Kingsbury was married on October 21, 1868, to Mary G. Hard, who was born in Broome County, New York, on September 21, 1846. Of this marriage, there were three children, Mattie J., Mildred A., and Elmer J.

A strong advocate of temperance, E. J. Kingsbury from the age of seventeen years was a member of one temperance organization or another. That he was a man of active intellect and professional versatility was evidenced by the fact that he studied law as well as medicine and became a qualified member of the bar of Minnesota, admitted on April 6, 1882, to practice law in all courts in the state. In 1884 he had been serving for four years as police justice of Le Roy.

Dr. Kingsbury is said to have died in 1885, at the age of fifty-one years.

Henry L. Knight was graduated from Rush Medical College in 1856. He arrived in Le Roy, Mower County, in 1884, where he became the outstanding physician, especially in the early nineties. In 1888 and again in 1895 he took graduate work at Rush Medical College, and in 1896 studied at the University of Bonn, Germany. In 1895 he sold his practice to Dr. Milan J. Hart with the intention of practicing in Adams. The exact sequence of his travels is not clear, but evidently he was in Adams for a time "before leaving for the Klondike." He again returned to Adams and practiced there until probably 1903, when he removed to California.

Dr. Knight was licensed in Minnesota on September 18, 1884, receiving certificate No. 961 (R). He was admitted to the Minnesota State Medical Society in 1886. An early member of the Mower County Medical Society, he was listed in 1903, in a roster of the county society that appeared in the *Transactions* of the state society, as in Adams.

David Kyts (sometimes seen Kyto), a "thorough graduate" of the Physio-Medical College of Indianapolis, Indiana, came to Brownsdale in the summer of 1883. After a few weeks, perhaps months, he left for Michigan. There seems no

doubt that he was the Dr. David V. Kyts, a graduate of the Physio-Medical College of Indiana, at Indianapolis, in 1882. He was listed in 1886 as in Grand Rapids, Michigan; his name did not appear after that year.

— **Lafayette,** believed to be a native of France, married, about forty years of age, came to Lansing, Mower County, from Red Wing, Goodhue County, in the autumn of 1866. Of the eclectic school, he carried on a successful practice in Lansing for about three years before removing to Missouri.

O. M. Landon practiced for a short time in Taopi in 1882. Dr. O. M. Landon, a graduate in 1882 from the State University of Iowa, was listed from 1886 to 1890, inclusive, as in Lawyer, Chickasaw County, Iowa. In 1893, listed as Dr. Oren M. Landon, he was in New Hampton, Iowa.

A. J. Lewis practiced at Rose Creek in the middle nineties. In 1898 Dr. Arthur J. Lewis, a graduate in 1895 from the Medical Department of Hamline University, was in Mora, Kanabec County, Minnesota.

Charles F. Lewis, according to Armstrong, was an oculist who began, in 1898, to spend one day a week in Austin, and thereafter, it appears, established his home there. It has been noted that Charles Fremont Lewis was born in 1868, was graduated from the Medical Department of Vanderbilt University, Nashville, Tennessee, in 1901, and was licensed to practice in Minnesota in 1903. He was an early member of the Mower County Medical Society and in 1910 served as president.

George L. Lewis, from Atchinson, Kansas, came to Austin in 1878 and remained a year or so.

W. D. Little opened an office at Sargent, Mower County, in 1896. He previously had spent a few years at Blooming Prairie, Steele County. On February 8, 1884, a Dr. W. D. Little, then of Mazeppa, Wabasha County, was licensed in Minnesota. He held certificate No. 808-1 (R).

Benjamin F. Lockwood, another practitioner about whom little has been learned, was a homeopathic physician and surgeon who came to Austin in 1898. He was graduated from Hahnemann Medical College and Hospital, Chicago, in 1885. The following year he was practicing in Honeoye, Monroe County, New York; from 1893 to 1896, inclusive, he was in the same county, at Rush. After the official listing in Austin, Minnesota, in 1898, his name did not appear.

Eugene W. McCord (1854-1913), to whom reference was noted as having had "a temperance drugstore," possibly in Austin in the early eighties, was in fact in Albert Lea, Freeborn County, for some time in the late seventies. Gullixon, in his notes on the medical history of Freeborn County, gave an interesting account of Dr. McCord's life: born in Titusville, Pennsylvania in 1854; spent his youth in Waverly, Iowa; was graduated from Jefferson Medical College, Philadelphia; was physician and druggist in Freeborn County beginning in 1877; later in Luverne, Rock County; and from 1884 in St. Paul. He was licensed in Minnesota by examination on December 31, 1883. In St. Paul, he was for a number of years on the staff of the City and County Hospital, became a member of the Ramsey County Medical Society in 1891, and of the state medical society the following year. He died in St. Paul in December, 1913.

— **McCormick,** it seems probable, was the "Dr. Cormick" mentioned in the general history of Mower County of 1884. See *Dr. Cormack,* in this list.

Alexander MacDonald (1856-1947) was in Austin, Mower County, from 1883 to 1897. He settled in Chatfield (Olmsted and Fillmore Counties) in 1901. A detailed biographical sketch appeared in the medical history of Fillmore County.

Born November 6, 1856, at Perth, Lanark County, Ontario, Canada, Alexander MacDonald was one of the five children of Mr. and Mrs. Joseph MacDonald, both of Scotch descent. In Canadian schools and colleges he received a superior preliminary education, and in 1883 was graduated with honor from McGill University with the degrees of doctor of medicine and master of chirurgery. In that year he began medical practice in Austin, Minnesota, and soon was appointed examiner for the United States Bureau of Pensions in that city. He was licensed in Minnesota on January 2, 1884, certificate No. 767 (R), and in 1887 was licensed to practice in Wisconsin and Iowa also. In the 1890's he served as Mower County physician.

Although by 1883 physicians of the established schools of practice had much decreased their use of the newspapers as a means of introducing themselves to the public, Dr. MacDonald used them freely to list his attainments and the diseases in which he specialized. He spent some time at the White Beaver Medical and Surgical Institute of St. Paul and La Crosse, with Dr. David Frank Powell (White Beaver), and in 1885, when he established his own dispensary in Austin, greatly increased the size and frequency of his statements in the local press.

For a time, Dr. C. H. Johnson, who came to Austin in 1884, was associated with Dr. MacDonald.

On September 30, 1890, Alexander MacDonald was married to Margaret Anna Forster, a native of Olmsted County and a teacher in the schools near Chatfield. Dr. and Mrs. MacDonald had one child, William Joseph Alexander MacDonald, of brief and brilliant career: an athlete, a graduate in law from the University of Washington, Seattle, and a valiant soldier in the Rainbow Division, World War I. He was killed in action in the Argonne on October 14, 1918. He was awarded the Distinguished Service Cross, and MacDonald Field, of the University of Washington, was named for him "for all time."

From 1897 to 1901 Dr. MacDonald practiced medicine in Ortonville, Big Stone County, where he served as secretary of the board of examiners of the United States Bureau of Pensions. In 1901 he settled in Chatfield and practiced there and in nearby villages. In his later years he retired from practice. Mrs. MacDonald died in August, 1943; Dr. MacDonald, in April, 1947.

William Henry McKenna (1843-1932) was a leading physician in southern Minnesota from 1872 until his death. He spent eight years in Caledonia, Houston County, and forty-nine years in Austin, Mower County.

William H. McKenna was born in Wheeling, West Virginia, May 1, 1843, one of the seven children of William Henry McKenna, native of Ireland, and Mary Ann McKenna, who was born in Scotland, of Scotch-Irish parents. His sisters were Maggie, Kate, Sarah, Alice and Mary Ann; he had one brother, John.

After completing his preliminary education in the schools of his native town, William H. McKenna studied medicine under the preceptorship of a physician of Wheeling. At the outbreak of the Civil War, while he was still studying medicine, he joined the Confederate Army, with which he served as a surgeon until he was taken prisoner at Paris, Kentucky, and was sent to Chicago to await an exchange of prisoners. After the close of the war he continued his medical study at Richmond, Virginia, and thereafter he was delegated by the government to go as a physician into the Northwest.

In 1872, Dr. McKenna took graduate work at the medical school of the University of Michigan and at the same time served on the faculty as assistant professor of anatomy. In that year, on completion of his work at the university, he obtained his license (exemption certificate No. 192-3) to practice medicine in Minnesota and settled in Caledonia, Houston County. In this period he was married to Mary Ellen King, a school teacher, who was born at Louisville, Kentucky, of Irish parents. Dr. and Mrs. McKenna had four children: Paul, Mayphine, Estella and Jay.

In Caledonia, Dr. McKenna entered into active professional life in the conduct of a widespread practice and in civic responsibility. He served as county physician, as local health officer, and in 1881 as county coroner. He kept a large stable, in order that he might answer calls at all hours, in all seasons, and at the same time protect his unusually fine horses, which he cherished, by changing teams every few hours. In later years, his elder son Paul accompanied him on his rounds, driving the team. Dr. McKenna's experiences in practice, in Houston County and in his earlier years in Mower County, were the arduous and hazardous ones of the true pioneer physician.

In 1883, Dr. McKenna moved with his family from Caledonia to Austin, and in the latter city and community he continued in heavy general practice. A man of wisdom, tolerance, and sympathetic understanding, an able and ethical physician, he was identified with civic and medical progress. In Austin he served as city physician. He was an early member of the Mower County Medical Society, and was a member of the Minnesota State Medical Association and the American Medical Association. He was a member of the Catholic Church and a generous

contributor to charitable and educational institutions. Politically, he was a Democrat. His family and his profession were his chief interests. Farming became a practical avocation. In fishing, he found his favorite recreation.

When Dr. William H. McKenna died in Austin April 26, 1932, of coronary disease, he was survived by his wife, his sons and his daughters. Mrs. McKenna died in 1933. In the early nineteen forties Paul K. McKenna, physician and surgeon, was practicing in Mount Sterling, Kentucky, and Jay K. McKenna, physician and surgeon, and Mayphine (Mrs. Joseph) Graf and Estella McKenna were in Austin.

In 1957, Dr. Jay K. McKenna continued in practice in Austin and had in association with him his daughter, Dr. Elizabeth McKenna, a graduate in medicine from the University of Minnesota in 1949. Mrs. Graf and Miss McKenna continued to make their home in Austin. Dr. Paul K. McKenna died in 1954. His son, Dr. William Henry McKenna, a graduate of the University of Louisville, succeeded him in practice in Mount Sterling, Kentucky.

Otto C. Maercklein, born in 1874, was graduated from the Milwaukee Medical College in 1897. On June 16, 1898, he was licensed to practice medicine in Minnesota, receiving state certificate No. 921. At about that time, it is believed, he opened an office for the practice of medicine in Adams, Mower County, where he remained until about 1905. Dr. Maercklein was an early member, and probably an organizer, of the Mower County Medical Society, and was a member of the Minnesota State Medical Association. By 1906, he had settled in North Dakota, first in Ashley; by 1914 he was established in Dickinson, and by 1927 in Mott, Hellinger County. He became a member of the North Dakota State Medical Association. In 1956, retired from practice, he continued to reside in Mott.

To date, unfortunately it has not been possible to communicate with members of the **Maercklein** family, several members of which have been physicians, two of them in Mower County, Minnesota.

Bernard G. Maercklein, born about 1848, was graduated from the Medical Department of the University of Pennsylvania in 1887, and probably soon after that came to Milwaukee, Wisconsin. He was one of the founders of the Milwaukee Medical College and held the chair of oral surgery. Later he was professor of oral surgery at Marquette University. He was a member of the Wisconsin State Medical Society. He died in the Radium Hospital, Milwaukee, September 30, 1915, from carcinoma, aged sixty-seven years. He was licensed in Wisconsin through the "years of practice" section of the Medical Practice Law of the state.

Charles J. Maercklein was born in 1876 and was graduated from the College of Physicians and Surgeons, Milwaukee, in 1902. He was licensed in both Wisconsin and Minnesota, in the latter state on April 17, 1903, receiving certificate No. 1595. Dr. Maercklein practiced medicine in Le Roy, Mower County, from 1903 or 1904 to about 1908. By 1909 he was in Lidgerwood, North Dakota; in 1916 in Gackle, that state; and in 1918 in Bowman. In 1927, he was listed as in Elk Mound, Wisconsin; in 1940, Sheboygan; in 1956, Red Granite.

A. G. Maercklein was graduated from the College of Physicians and Surgeons, Milwaukee, in 1902. He was licensed in Minnesota on October 24, 1902, certificate No. 1574. From 1927 to 1956 he was listed in official directories as of Ellendale, North Dakota.

Ivan Rudolph Maercklein was graduated from the Milwaukee Medical College in 1903 and was licensed in Minnesota October 21, 1914, receiving certificate No. 4067. In 1927 he was in Wishek, North Dakota. His name did not appear in directories of 1956.

Bernard Webb Maercklein was a graduate in dentistry in 1911 in Wisconsin.

Josef (or Joseph) Mark, believed to have been the first Jewish physician to practice medicine in Minnesota, came to the United States from Russia in 1877. The son of a physician, Dr. Haskel Mark, he was born in 1852 in Pren (later Kovno or Kaunas), Lithuania. He was graduated in 1871 from Kovno Medical College, and on September 4, 1872, was licensed by "Savalskajo Gubernia Administration," and thus entitled to practice throughout the Russian Empire.

On October 15, 1883, Dr. Mark, then in Minneapolis, received Minnesota license No. 166 (R). At about that time, with his wife he settled in Caledonia, Houston County, where he practiced for several years. In 1886 the family was in St. Paul; a son, Daniel Benjamin Mark, was born there in that year. Dr. Mark then had a drugstore on Reany Street, St. Paul; it is not clear that he was practicing medicine. There is record that he practiced at different times in various counties of the state: in the early nineties in Minneapolis, Hennepin County, and again later for many years; in 1896 in Lyle, Mower County; 1903 in Marshall County; 1909 in Hibbing, St. Louis County.

Dr. Mark died in Minneapolis in 1926, at the age of seventy-four years. He had retired from practice four years before his death, after forty-five years as a physician in Minnesota. In the early years, members of the family have said he was a true

pioneer physician who experienced the typical vicissitudes of the time; scanty equipment, bad roads and weather and, in winter, travel in primitive conveyances with improvised heaters.

Dr. Mark was survived by his wife, who in 1956 continued to make her home in Minneapolis, and by his son, Dr. Daniel B. Mark (1886-1948), who for thirty-four years was a practicing physician of Minneapolis, and by grandchildren. A sister and a brother, Sam, were residents of Minneapolis. In 1957, Dr. Vernon H. Mark, formerly in military service, son of Dr. Daniel B. Mark, was in practice in Minneapolis.

H. D. Martin, in 1879, started an Eye and Ear Infirmary in Austin in which patients could be "treated by the week or by contract," with satisfaction guaranteed and consultation free.

John Lewis Martin (1806-1885) was from 1856 until his death, farmer, Wesleyan Methodist minister and actively practicing homeopathic physician in southern Minnesota, successively in Mower, Olmsted and Dodge Counties. He has been mentioned as in Fillmore and Jackson Counties also, but record of such residence has not been observed. Dr. Martin has been described as a small, wiry, bewhiskered man, dignified and respected, who commonly rode on horseback to make his professional calls and to relieve in the pulpits of his brother clergymen.

Born September 17, 1806, in Madison County, New York (sometimes given as Albany, Albany County), John Lewis Martin was one of a family of seven children whose parents were John L. Martin, from the north of Ireland, a teacher in a school for boys, and Mary Martin, a seamstress, a native of Edinburgh, Scotland. In early adult years he was a clerk in a store. His medical training is not known; one of his descendants recalled that he had a medical certificate that had been issued in New York State. John L. Martin was married in Albany, New York, to Emmeline J. (the name later was changed to Elizabeth Ruth at his request) Berghes, a teacher of music. About 1850 he came with his wife and children to Valparaiso, Indiana, and in 1856, by ox cart, into Mower County, Minnesota, where he farmed in section 15, Frankford Township, and practiced medicine over a wide territory. It is said that he conducted the first neighborhood school of the community in his log house, and that during the diphtheria epidemic of 1866 he rendered faithful service. Mrs. Martin died December 10, 1870, in her fifty-first year, and was buried in Frankford Cemetery. Still in Frankford in 1874, there is some record that during the next two years Dr. Martin and his children were living in or near the village of High Forest, Olmsted County.

For several months in 1876 and early 1877, a Dr. Martin, homeopath, was in Eyota, Olmsted County, in partnership with Dr. Isaac M. Westfall. In 1877 Dr. John L. Martin settled in Wasioja, Dodge County, so that his eight children (three had died in infancy) might be educated at the Wasioja Seminary. In Wasioja Dr. Martin continued to preach and to practice medicine. He died in Wasioja from cardiac disease on September 22, 1885, and was buried beside his wife in Frankford Cemetery. In 1942 his children were long since dead; several grandchildren and great-grandchildren survived.

— **Mattson,** in 1887, probably an itinerant, was one of the several practitioners in Mower County, and perhaps in Freeborn County, about whom information has not been gained.

Simeon Paul Meredith (1852-1930), homeopathic physician, a graduate of the Hahnemann Medical College and Hospital in Chicago in 1882, from that year until his death was a respected physician in various counties in southern Minnesota. Detailed biographical notes appeared in the medical history of Fillmore County.

Born on January 27, 1852, at Middleton, Wisconsin, Simeon P. Meredith received his early education in the local country school, studied at the University of Iowa, later taught the rural school near Middleton, and next qualified as a physician. He began practice in the middle seventies in Jefferson, Wisconsin, and later was in Spring Green, that state.

Shortly after his graduation from medical college in 1882, he came to Minnesota because of ill health and first practiced in Austin, Mower County. Under the Affidavit Law of 1887, then in Plain Prairie, he was licensed in Minnesota. By 1888 he was in Spring Valley, where he practiced nearly ten years. He may have gone from there to Owatonna, Steele County. In February, 1899, he moved to

Pleasant Grove, Olmsted County, to assume the practice and drugstore of Dr. M. T. Bascomb who had died the previous month; there he served as county physician for the village and the township. In the spring of 1902, he returned to Mower County, to Grand Meadow, but by October, that year, he had moved to Windom, Cottonwood County. After several years, he went to Garden City, Blue Earth County. In 1908, he retired from practice and made his permanent home in Mankato.

Before leaving Wisconsin, he was married to Fannie Glasier, of Bedford, Ohio. There were two children of the marriage, Eva L., who died in 1934, and Harlan.

Dr. Meredith died in Mankato on September 1, 1930. He never had been in good health, and for many years had suffered from bronchitis and asthma. He applied his limited strength exclusively to the practice of his profession.

Melvin C. Millet (1868-1907) practiced two years in Le Roy in the late nineties in partnership with Dr. Milan J. Hart.

He was born September 22, 1868, in Sumner Township, Fillmore County, near Hamilton, the son of Mr. and Mrs. Roscoe G. Millet. After attending the district school he studied two years at the Winona Teachers College, taught district school one year, and read medicine for one year with Dr. Rollo C. Dugan of Dover, Olmsted County. In the autumn of 1892, he entered the medical school of the University of Minnesota, from which he was graduated with high honors in June, 1895. He was licensed by examination in Minnesota on June 11, 1895, and received certificate No. 529 (R). After an initial practice of a year and a half in Dover, he joined his old friend and classmate, Dr. Milan J. Hart, in Le Roy, Mower County. Late in 1898, he became a member of the staff of the Drs. Mayo, Graham and Stinchfield of Rochester (group called "Mayo Clinic" beginning in 1912).

Melvin C. Millet was married on June 12, 1901, to Mary A. Frick, of Minneapolis, a daughter of Mr. and Mrs. Thomas W. Frick of that city. Dr. and Mrs. Millet had one child, Roscoe Frick Millet.

When Dr. Melvin C. Millet died at his home in Rochester from Bright's disease May 7, 1907, his brilliant professional career had measured only twelve years. He was survived by his wife, his son, and his parents, two sisters, and one brother. His son, Roscoe F. Millet, a graduate of Northwestern University in 1930, has practiced medicine in Macomb, Illinois, since 1942.

P. E. Minckler practiced in Brownsdale in the later seventies. This physician perhaps was the "Dr. Minkler" mentioned in the history of Mower County of 1884, who came to Brownsdale from Westfield, Wisconsin, some time in 1875. He was a graduate of a medical college in Canada, remained in Brownsdale a short time, and returned to Wisconsin.

— **Mitchell** has been mentioned as having practiced in Grand Meadow. The name probably refers to Dr. Ralph Sidney Mitchell, born in 1874, licensed in Minnesota in 1903, then of Grand Meadow.

George E. Moon is said to have been in Le Roy in 1869. If so, his stay was brief, for in the same year he studied with Dr. A. C. Wedge in Albert Lea, and soon afterward was practicing in Geneva, Freeborn County. After about a year, he left for Yankton, Dakota Territory, where in 1884 he died by his own hand, from an overdose of morphine.

In the late 1890's, there were listed in medical directories three practitioners of the name *Mary E. Morrison,* one of them Mrs. Mary E. Morrison, and a Mrs. Mary Morrison.

Mary E. Morrison who was in Austin, Mower County, around the turn of the century was almost certainly Mrs. Mary E. Morrison, a graduate from the Physio-Medical School, in Indianapolis, in 1897. It is believed that this practitioner and Mrs. Mary Morrison were the same person; Mrs. Mary Morrison was listed in 1898 as in Anderson, Madison County, Indiana, "no report on qualifications." In that year, or in 1899, Mrs. Morrison came to Austin; her name appears as a practitioner in this city in 1900 and 1902 but not in 1904.

Of the other two practitioners of this name, one was a graduate of the Medical Department of Howard University, Washington, D. C. in 1886, and apparently continued in practice in that place. The second physician of this name was a graduate of the University of California in 1894, and was in practice in San Francisco at least through 1900.

D. F. O'Connor, who practiced medicine in Grand Meadow from perhaps 1893 to 1899, inclusive, was, there seems little doubt, Dr. Dennis F. O'Connor, a graduate of the College of Medicine and Surgery of the University of Minnesota in 1890. He was listed in 1896 and in 1900 as in Grand Meadow. In 1897, he was admitted to membership in the Minnesota State Medical Society. In 1898, Dr. O'Connor sold his practice to Dr. Willard W. Freeman, who came from Caledonia, Houston County, to Grand Meadow. Members of Dr. Freeman's family recall that Dr. O'Connor remained in the village for some time after Dr. Freeman began practice there. In 1900, Dr. O'Connor was in St. James, Watonwan County, where he remained through 1904. By 1906, he was in Maxbass, North Dakota.

In a revised roster of the Minnesota Valley Medical Association dated May 12, 1896, appears the name of Dr. F. O'Connor of St. James. It is possible that this was Dr. D. F. O'Connor and that he practiced in St. James both before his stay in Grand Meadow and afterward.

H. Pagin, an eclectic physician who announced himself as a graduate of the Medical Department of the State University of Missouri, practiced for a time in partnership with Dr. D. Strock in Austin in 1878. They advertised widely and were "specialists in chronic diseases." Dr. Strock left Austin that year for Indiana, and it seems a reasonable assumption that Dr. Pagin was not a long-term resident.

Homer Francis Peirson (1867-1938) practiced medicine in Austin forty-two years, from 1896 until his death.

Born at a farm home west of High Forest, near Stewartville September 11, 1867, he was the son of Frederick Moses Peirson (1834-1913), a native of Vermont, and Catherine Keyes Peirson (1836?-1912), who was born in Ireland. The only other child of the marriage, Alonzo, died in infancy in 1864.

In New England, the Peirson and Saxton forebears of Frederick M. Peirson were of English descent and served with the American forces in the Revolutionary War. Frederick M. Peirson and his older brother John Saxton Peirson when young boys came with their parents and other members of the family from Vermont to Ohio and later to Illinois and to Wisconsin. From La Crosse the two brothers came to Mower County in the summer of 1854 and filed on adjoining claims in what was later called the "Mile Strip" which, in 1857, was annexed to Olmsted County. These farms remained in the respective families for more than eighty-five years. In November, 1860, F. M. Peirson brought his bride to the substantial grout house which he had built on his claim. On their farm during the Civil War years, Mr. and Mrs. Peirson kept a tavern for convenience of travelers from Winona to western Mower County. In 1874, they moved to Rochester, where they ran the Stevens Hotel for three years. In 1877, they bought the Brown Hotel, in Grand Meadow, Mower County, which they operated and made their home until 1898, when they retired from business. In 1911, they moved to Austin.

In Grand Meadow, Homer F. Peirson grew up and received his preliminary education. He spent one year at Carleton College, Northfield, before entering the University of Minnesota, from which he was graduated in 1891. At the university he was a member of Theta Phi Fraternity, and was one of the editors of "The Gopher" in 1891. Thereafter he read medicine one year with Dr. Horace H. Witherstine, of Rochester, before entering Rush Medical College, from which he received his degree in 1895. On completion of his internship at St. Mary's Hospital, Minneapolis in 1896, he began the practice of medicine in Austin.

On June 14, 1898 Homer F. Peirson was married to Jessie Eleanor Allen, of Grand Meadow, whom he had known since childhood. Mrs. Peirson was the daughter of Mr. and Mrs. Gilbert Allen, who had settled in Grand Meadow in 1874. Mr. Allen operated a store and for several years was surveyor for Mower County.

In Austin, Dr. Peirson devoted himself to his profession. His offices were over Wold's Drug Store, at the corner of Main and Bridge Streets. Although he took little part in local politics, he served as county physician, and as county coroner for many years. Active in fraternal organizations, he was a member of the Independent Order of Odd Fellows for more than thirty years, Aerie physician for the Fraternal Order of Eagles for many years, and medical examiner for a number of other organizations.

In 1896, Dr. Peirson was president of the original or "old" Mower County Medical Society. When the present county medical society was founded, in response to the program of organization started in 1902 by the state medical society, he was one of the first members, and was one of the early presidents of the group. He was a member of the Minnesota State and the American Medical Associations.

His two great interests in life were his profession and his family. A skilled and ethical physician, friendly and helpful, he held the respect and liking of physicians and laity. In his middle years he was of rugged physical appearance, had bushy eyebrows, and wore a heavy moustache; at times he affected a rather brusque manner which, however, misled no one. He was a devoted husband and father, always kind and considerate in his home, and was a genial host to guests. The family were members of the Congregational Church.

In the last two years of his life, Dr. Peirson was in failing health, but refused to give up his practice of medicine, and went daily to his office. It was there that he was stricken with the cerebral hemorrhage from which he died a few hours later, March 24, 1938. He was survived by his wife and two daughters, Helen (Mrs. Cyril B. Bell) and Marion (Mrs. A. M. Steenerson) and five grandchildren. In 1957, Mrs. Peirson continued to make her home in Austin; Mrs. Bell was in Huntington Beach, California, and Mrs. Steenerson in Minneapolis.

Thomas Phillips, Canadian born, a graduate of the University of Chicago in 1880 and of the Hahnemann Medical College and Hospital, Chicago, in 1882, began the practice of medicine in Austin in May, 1882. Local comment at the time was, "Dr. Phillips is a young man of good attainments, and promises to make a successful physician." He specialized in the diseases of women and children. On December 31, 1883, he was licensed in Minnesota, under certificate No. 657 (H). In 1884, in Austin, he served as chairman of the board of health. In 1888, according to local record, he removed to Iowa, although in 1890 he still was listed in a medical directory as in Austin. In 1893, he was in Raymond, Blackhawk County, Iowa; by 1900 he was in Iowa Falls, Hardin County.

John J. Platt (1875-1927) began his initial practice of medicine in Dexter, Mower County in 1895, the year of his graduation from the College of Medicine and Surgery of the University of Minnesota. He was licensed in the state in June, 1895. Local record is that he removed from Dexter to Rudd, Iowa; his stay in Iowa was brief, for in 1896 he was practicing in Minneapolis.

From 1898 until his death, he was a resident of St. Paul. On October 31, 1883, he was admitted to membership in the Ramsey County Medical Society. In the files of the society is his application for membership, in his handwriting, in which he stated that he was born in Rochester, Minnesota, on February 26, 1875; that he was graduated from a St. Paul high school, and, as noted, from the University of Minnesota in 1895. During World War I, he served with the Armed Forces of the United States as a major in the Medical Corps.

Dr. Platt died in St. Paul on September 12, 1927, from pulmonary tuberculosis, after a long illness. From the record in medical directories, one may assume that he had retired from practice some years before his death, or that for a long time his professional activity had been intermittent.

Albert Plummer (1840-1912), a distinguished physician, practiced medicine in the community of Hamilton, Fillmore County, twenty-four years, and in Racine, Mower County, eight years, beginning in 1893. The last year of his life he spent in Rochester. A detailed biographical sketch of Dr. Plummer appeared in the medical history of Fillmore County.

Born at Auburn, Rockingham County, New Hampshire, September 7, 1840, Albert Plummer received his early schooling at Auburn and at the Kimball Union Academy, New Hampshire. He studied medicine under the preceptorship of his father, Dr. Nathan Plummer, and the special knowledge thus acquired proved useful during his three years of active service in the Civil War. In the autumn of 1865, he entered the medical department of Dartmouth College; later he transferred to the medical school of Bowdoin College, Brunswick, Maine, from which he was graduated in 1867.

In 1869, Dr. Plummer began practice at Hamilton. He soon became a member of the Fillmore County Medical Society and of the Minnesota State Medical Society (reorganized that year) and cooperated with the State Board of Health (established

1872). In 1882-1883, he served in the state legislature as representative from his district. On January 15, 1884 he received state medical license No. 737 (R).

He was married to Isabel Steer at Sumner, Fillmore County October 10, 1872. To this marriage were born four children, two of whom died in infancy. Henry Stanley Plummer (1874-1936) and William Albert Plummer (1883-1949) became able physicians, known for their work as members of the staff of the Mayo Clinic.

After settling in Racine in 1893, Dr. Plummer continued his extensive intercounty practice. For two years (1898-1900) he was aided by Dr. H. S. Plummer. In 1911 Dr. and Mrs. Albert Plummer made their home in Rochester; Dr. Plummer died March 20, 1912; Mrs. Plummer January 15, 1936.

Henry Stanley Plummer, elder son of Dr. Albert Plummer, was born March 3, 1874, at Hamilton, Fillmore County. He received his early education in the schools of Racine and Spring Valley. On graduation from the medical school of Northwestern University, in 1898, he joined his father in practice at Racine. In 1900 he became a member of the staff of the Drs. Mayo in Rochester. He died in Rochester December 31, 1936. See also in the medical history of Olmsted County.

J. F. Preston, a native of Connecticut who came to Minnesota from Youngstown, Ohio, has been mentioned as having been in Brownsdale, Mower County, in the late eighteen seventies. In 1878, according to a local newspaper of that year, he was in Alden, Freeborn County, "a pleasant and agreeable gentleman," physician and surgeon, who specialized in eye work and also ran a drugstore. In 1880, he sold the store to Dr. R. V. Perry of Alden and returned to Ohio. Later, he came West again, to Decorah, Iowa, for a few years, it was said, and in April, 1889, once more established himself in Alden, bought a drugstore, and built up a good medical practice. After a short time he returned to Youngstown, Ohio.

Of interest is a recent statement that Dr. J. F. Preston was listed in a directory of 1890, "no report." In 1893, Dr. James F. Preston, of Youngstown, Ohio, was listed officially as a graduate from the American University of Pennsylvania (Philadelphia) in 1875; in 1896-1898 Dr. Preston was listed as in Mason City, Iowa.

D. P. Putney was listed in an official directory of physicians and surgeons, in 1886-1890, as practicing in Frankford, Mower County. His professional qualifications were not stated. Other mention of this practitioner has not been noted. At the time of his residence in Frankford, the village, a few miles from Grand Meadow, had a population of one hundred, which decreased in the next few years to fifty.

Samuel H. Rabuck, a graduate from Rush Medical College, Chicago, in 1896, practiced in Lyle, Mower County, in 1897-1898. In 1900, he was in Bloomville, Delaware County, New York, and from 1902 through 1904 in Bovina Center, in the same county. He was one of the many physicians who, it seems, were briefly in one county or another of the state before the turn of the century.

F. Q. Remington is said to have been in Austin in 1881, and in Grand Meadow for a short time. "He left the next summer."

Calvin Hubbard Robbins (1840-1900) was well known in southern Minnesota for many years, in Austin for two years. A detailed biographical sketch of Dr. Robbins appeared in the medical history of Fillmore County.

Born in St. Lawrence County, New York December 20, 1840, Calvin H. Robbins was one of the five children of Marcus Robbins and Fanny Hubbard Robbins, both of English descent, of distinguished ancestry. In 1859 the family came to Fillmore Township, Fillmore County, Minnesota. Calvin Robbins went to school in Fillmore and Chatfield, and for a year or two taught in the rural schools of his community before entering on three years of medical study in the office of Dr. Luke Miller, of Chatfield. During the Civil War he served with the Union Army. On his discharge from military service in October, 1864, he enrolled at the medical school of the University of Michigan; a year later he transferred to the Medical College of Keokuk (Iowa), from which he was graduated in 1866. In that year, he began the practice of medicine in the village of Fillmore, and became a charter member of the Fillmore County Medical Society (October, 1866).

In November, 1866, Calvin H. Robbins was married to Rosalia R. Mosher, a school teacher, formerly of Canton, New York. Dr. and Mrs. Robbins made their home in Fillmore for nine years where their five children were born. In 1875 the family moved to Wykoff where they remained for twenty years.

In 1871, Dr. Robbins became a member of the Minnesota State Medical Society, and in the ensuing years served on many committees of the society. After the passage of the "Diploma Law" of 1883 he received certificate No. 550 (R) dated December 31, 1884. During the eighties, he served as an examining surgeon for the United States Bureau of Pensions of Fillmore County. In 1895, Dr. Robbins moved to Spencer, Iowa, where he owned and managed the *Spencer Reporter*.

By 1898 Dr. Robbins had left the newspaper field and had settled in Austin, Mower County, where he successfully resumed the practice of medicine and where he was known as "a gentle and courteous physician of the old school." He died in Austin February 28, 1900, from angina pectoris, survived by his wife, five children, and two brothers.

Samuel W. Rutledge, a graduate of the Homoeopathic Medical College of Missouri in 1876, came in 1879 from Cresco, Iowa, to Rose Creek, Mower County. Record is sparse. June 12, 1885, he was licensed to practice in Minnesota as possessor of certificate No. 1067 (H). On July 15, 1885, then of Grand Forks, Dakota, he was licensed to practice in Dakota Territory.

George Jacob Schottler (1870-1951) was a valued citizen and physician of Dexter, and Mower County, for fifty-four years, from 1896 until his death.

Born at Rockfield, Washington County, Wisconsin November 5, 1870, George J. Schottler was the son of Nicholas S. Schottler and Anna Regenfuss Schottler. He received his early education in the schools of his native county, and thereafter took a teacher's course at the normal school of the University of Indiana, at Valparaiso, Indiana, from which he was graduated with the degree of bachelor of science in 1892. After teaching a few terms of school, he began the study of medicine, and in 1896 was graduated from Rush Medical College, Chicago. In that year he began the practice of medicine in Dexter and the community. Throughout his career he kept in touch with medical advance by graduate work, outside study, and activity in medical societies.

Dr. Schottler was interested in the organization of St. Olaf Hospital, Austin, and was one of the first to avail himself of its facilities in his practice. He was founder of the Mower County Medical Society, its first treasurer, and later its president; was a member of the Southern Minnesota Medical Association, the Minnesota State Medical Association, and the American Medical Association. In Dexter he served as health officer, and on the board of education, for two terms each as treasurer and as president. He was vice-president of the First State Bank of Dexter. He attended the Community Church of Dexter.

In 1942, Dexter and community honored Dr. Schottler on his seventy-fifth birthday with a party sponsored by the American Legion Auxiliary of the village. March 26, 1947, Dr. Schottler was an honored guest, together with Dr. O. H. Hegge, of Austin, and Dr. A. E. Henslin, of Le Roy, at a dinner given by the Mower County Medical Society, at Austin, in tribute for the more than fifty years of devoted service each of the honored guests had rendered Mower County as a physician and surgeon. The reminiscences of their early experiences in practice, of the three deans of medicine, were a highlight of the occasion.

On September 12, 1900, at Dexter, George J. Schottler was married to Kathleen Vermilyea. Dr. and Mrs. Schottler became the parents of four children, three sons and a daughter. When Dr. Schottler died February 15, 1951, he was survived by his wife and by the four children: Dr. Max E. Schottler, of Minneapolis; Kenneth, of Duluth; Jesse, of White Plains, New York; and Kathryn (Mrs. P. C. Remington), of Chicago. Mrs. G. J. Schottler died June 26, 1955.

Dr. M. E. Schottler said of his father, "His only hobby was work at the practice of medicine. He had a wonderful garden and enjoyed it immensely, he vacationed at Lake Ponto and loved the vacation, but still always worked."

Rollon W. Simmons, a graduate of the Cincinnati Medical College, was the first physician to practice at Dexter, Mower County. He came in 1873, remained two or three years, and returned to Indiana, his former home. His successor in Dexter was Dr. Lyman D. Jackson, in 1877, who removed to Grand Meadow in 1879.

L. Douglas Smith was a "great magnetic healer," self described, who imposed on both Austin and Albert Lea in 1894. Not eligible for inclusion in this list of physicians, he is mentioned merely as one of a type. Of possible interest are the

following listings, all with "no report," of L. D. Smith: in 1896 in Wausau, Wisconsin; 1898, La Crosse, Wisconsin; 1900 Los Angeles, California, and Longmont, Colorado. The name did not appear in 1902.

Rensselaer Soule was a pioneer physician who came to Lansing Township, Mower County in 1865. He was born in Fairfield, Franklin County, Vermont, one of the ten children of Salmon Soule and Sara Soule. He was graduated in medicine from the University of Vermont, at Burlington, and thereafter practiced medicine in Vermont, first in Fairfield, later in North Fairfax, and in Canada. December 23, 1833 he was married to Susan Richardson of North Fairfax. Dr. and Mrs. Soule were members of the Episcopal Church. Of their seven children, two were born in Fairfield, and five in North Fairfax. The family traced descent from George Soule, a Mayflower passenger, and on the maternal side, from Miles Standish.

When Dr. and Mrs. Soule came to Mower County, they were accompanied, it is said, by their six surviving children, then grown, some of them married. In Lansing Township Dr. Soule bought a large tract of land which he divided among the children. A daughter, Bessie Soule, become the wife of Alvah E. Beadell, a farmer of the township. One of the sons, Rensselaer Soule, Jr., first settled in Lansing village and later moved on to a farm; his wife was Cornelia L. Hawley, of Mower County. Of this marriage, there were four children, one of whom was Herbert R. Soule, who on September 3, 1884, was married to Alice Padgett. Further record of the family has not been available.

Dr. Soule had not intended to practice medicine in Minnesota, but owing to the immediate local demand for his services as physician, he continued his professional work. In 1875, Dr. and Mrs. Soule made their home in Austin. Mrs. Soule died there in the spring of 1880, at the age of sixty-seven; Dr. Soule survived her until the autumn of 1880, when he died at the age of seventy-seven.

H. W. Spafford, who came to Mower County from Lake City, Wabasha County, spent part of 1875 in Austin.

James Phineas Squires was born at Dansville, Livingston County, New York August 25, 1851. In 1853, then in Wisconsin, he entered the United States Army as assistant surgeon of the 48th Regiment of Volunteer Infantry of Wisconsin. There is record that for two years, about 1870-1872, he practiced medicine in Blue Earth, Faribault County, Minnesota.

In 1872, Dr. Squires settled in Austin, Mower County. He had an extensive practice, which he sometimes dropped altogether, it is said, in order to devote his energies to his farm about eight miles south of the city. In 1880 he was admitted to the Minnesota State Medical Society; his name did not appear on the roster after that year. Although he has been listed unofficially as a homeopath, his Minnesota state license, dated April 16, 1884, was No. 867 (R). During his years in Austin, he was a member of the examining board of the U. S. Bureau of Pensions.

In 1887, Dr. Squires removed permanently to southern California. In unpublished notes on physicians of Steele County, a Dr. Squires is mentioned as practicing at Medford in 1880. It is possible that Dr. J. P. Squires may have been in Medford in the course of intercounty practice.

C. K. Stewart no doubt was **Charles K. Stewart,** a graduate of the University of Michigan Homeopathic Medical College in 1893, who came to Dexter, Mower County, in that year. In notes on the medical history of Olmsted County "Dr. Stewart," a homeopath, was mentioned as having been in Byron. An elderly citizen of the community expressed the belief that "Doc Stewart" had been in Byron briefly in the early nineties, recalled his personal appearance, that he once was called in an emergency, and that he soon went on "west."

Recent information makes the record clearer. After about two years in Dexter, Dr. Stewart removed to Iowa, where in 1896 he was in Washington, and in 1898 in Waterloo. In 1900, he again was in Mower County, in Brownsdale. In this period he supplied the following data about himself: "Member N. W. Surgical Acad. of Homo. Phys.; Ex-Secr. and Treas. Cedar Valley Homo. Med. Soc.: Ex-health officer, Dexter, Minnesota, and Med. Examiner M. W. of Am. Mill." Official listings place this practitioner in Byron, Olmsted County, in 1902, possibly his second stay in that village; in 1904 in Janesville, Waseca County, where he remained through 1910. Thereafter, he was not listed.

Thomas Stringer, another physician about whom little is known, practiced at Lansing, Mower County, about 1873.

D. Strock practiced in Austin for a while in 1878, and then left for Indiana. For a time, he was in partnership with Dr. H. Pagin, an eclectic practitioner, who probably was in Austin a short time. Drs. Strock and Pagin advertised freely in the newspapers. Both perhaps should be classed as itinerant practitioners.

— **Tanner,** a homeopath, practiced in Lyle for a short time in 1870.

French W. Thornhill, son of Samuel Payne Thornhill, M.D. (*q.v.*), was born in Coshocton County, Ohio, on July 18, 1843. At the age of nineteen years he entered the Union Army and during the Civil War served as assistant surgeon in the Wisconsin regiment in which his father was regimental surgeon. It seems obvious that Dr. Samuel P. Thornhill had been and continued to be his son's preceptor. After the war, French W. Thornhill entered the Cincinnati Medical College, from which he was graduated in 1869. In that year, he accompanied his father to Austin, Mower County, and there practiced medicine in partnership with him for three years. At the same time, he managed a farm in sections 5 and 6 of Austin Township that his father had bought from John I. Wheeler, who was moving into Freeborn County.

In 1872, Dr. F. W. Thornhill settled permanently in Spring Valley, Fillmore County, with his wife and children, and there continued as a practicing physician. In 1883 he received an exemption certificate on the basis of years of practice. He died at his home February 4, 1912.

Samuel Payne Thornhill (1821-1879) was born in Rockingham County, Virginia, March 21, 1821. Left an orphan when a small child, he lived for a few years with relatives, but early in life was thrown on his own resources for support and education. That he became an able physician and surgeon manifests his great native ability. He studied medicine under a preceptor in West Carlisle, Coshocton County, Ohio; in that community he began medical practice and married. His sons French W. Thornhill and Ampstead S. Thornhill (later a farmer in Mower County), and a third child were born in Ohio. While his children were young, Dr. Thornhill moved with them to Horicon, Wisconsin, and from there to Watertown, Wisconsin. His wife had died, and in Watertown he married again. Of the second marriage, there were two children. In 1848, the family moved to Janesville, Wisconsin, where Dr. Thornhill was in partnership with Dr. Treat, who later was well known in Chicago. In 1855, Dr. Thornhill settled in Hudson, Wisconsin, for seven years. When the Civil War began, he was made regimental surgeon of the 8th Wisconsin Volunteer Regiment, the Eagle Regiment under Colonel Murphy, and in 1862 he became brigade surgeon.

In the winter of 1869-1870, he came to Austin, Mower County, with his son Dr. French W. Thornhill, and there practiced for ten years, the first three with his son. Dr. S. P. Thornhill made his home with Mr. and Mrs. Alonzo Fairbanks. During the last few years of his life, Mrs. Fairbanks studied medicine under his preceptorship and later took her degree (see Ellen Backus Fairbanks). Dr. Thornhill was skillful, untiring in his service to the sick, and was well loved. At one time, it was reputed that he had the largest practice in the city.

When Dr. Thornhill died in March, 1879 from gastric hemorrhage, which perhaps, it was said, was induced by his addiction to alcohol, Ellen Backus Fairbanks wrote of him, in part, in the *Austin Register* of March 13: ". . . If he had faults, he also had virtues. To his friends he was generous, kind and true. A tender father to his children, and second to none in his professional acquirements, his loss to us is a public calamity."

S. P. Thornton practiced in Austin from 1869 until his death in 1879. He had been a regimental and a brigade surgeon in the Civil War. From the similarity in military record and in period of residence in Austin to those of Dr. S. P. Thornhill, it seems probable that the name was a misprint of "S. P. Thornhill."

Charles B. Thrall, a native of Pittsfield, Massachusetts, was a graduate of Rush Medical College, Chicago, in 1868. In a general history of Mower County, Minnesota (1884), it was stated that in 1874 Dr. C. B. Thrall came with his wife from Leon Valley, Wisconsin, to Le Roy, where he entered into partnership with Dr. E. J. Kingsbury. At one time, he served as county physician. Mrs. Thrall died at Le

Roy within a short time after their arrival in the village, and not long after her death Dr. Thrall left for La Crosse, Wisconsin, or vicinity, where, in 1884, he was "enjoying a lucrative practice." In the period 1886-1890, he was listed as living in Galesville, Trempealeau County, Wisconsin; in 1886, his name appeared on the roster of the Chippewa Valley Medical Association. He was not listed in medical directories in 1892.

A. Thrane was in Austin around 1874. He may have practiced medicine; "he probably ran a drugstore."

W. E. Todd, a son of the Rev. James D. Todd, was born in Wisconsin in 1861, and was graduated in 1890 from the Chicago Medical College. He practiced medicine in the logging and mining districts of Neaunce, Upper Michigan, and later in Madison, Mower County, Minnesota. In 1896, he went to Albert Lea, Freeborn County, to join his brother, Dr. J. M. Todd, in practice. In the medical history of Freeborn County, Gullixon gave full biographical sketches of Dr. W. E. Todd, Dr. J. M. Todd, and other well-known members of the family.

— **Torkelson** came to Lyle, Mower County, in 1882. There seems little doubt that he was the "Dr." Torkelson, a druggist, who in 1882 opened a drugstore in Hartland, Freeborn County. As Gullixon said, in those days all druggists prescribed medicine over the counter and were called "doctor." In 1885 a local newspaper stated: "Dr. Torkelson, our doctor, druggist and postmaster, has died." Death was due to consumption. About 1909, Peter T. Torkelson, M.D., came to Lyle.

Oscar H. Trenkler, a homeopathic physician, mentioned elsewhere as having been in Mower County, perhaps never practiced in the county other than in the course of intercounty calls. He was a graduate in 1854 from the University of Giessen, Germany, who came to the United States about 1857. In August, 1879, then from Portage, Wisconsin, he began practice in Albert Lea, Freeborn County. In May, 1881, he settled in Mankato, Blue Earth County, and was still there in 1886-1890, as listed in Polk's directory of physicians and surgeons. His name did not appear in official lists in 1893.

A. Truane, the first physician in Lyle, Mower County, settled there in 1870. He was said to be of the "old school" and a good physician. From Lyle, he went to Eau Claire, Wisconsin, where, in 1884, he was still in practice.

Ernest W. Tryon, a graduate of the Bennett Eclectic Medical College in 1885, practiced a few years in Austin, Mower County, in the nineties. There is uncertainty about the length of time he spent in different places of residence, but listings in official medical directories indicate the following approximation: Minneapolis, 1885-1890, perhaps later; Austin, 1895-1898; Dassel, Meeker County, about 1900-1903. From Dassel he went to Minneapolis, where he practiced until his death. Dr. Tryon was licensed in Minnesota on April 20, 1885, and received certificate No. 1039 (E). He died March 5, 1927, at the age of seventy, from coronary sclerosis and diabetes.

H. T. Turner, of Lyle, Mower County, was listed in an illustrated atlas of Minnesota, in 1874, as a druggist, who was born in Oneida County, New York, date not given. Armstrong commented that H. T. Turner, a homeopath and a dealer in drugs and medicines, came in 1871 to Lyle, where he reputedly had a "well-fitted and tasty drugstore."

It is probable, but not proved, that he was the Dr. Henry T. Turner who was in Kasson, Dodge County, at intervals between 1875 and 1889, when he went to Walla Walla, Washington. This man was born in New York July 16, 1837; was graduated in 1862 from the old Eclectic Medical College of Pennsylvania at Philadelphia. In Minnesota, date unknown, he was married to Miss Abbey Potter of Mower County. Again speculatively, Miss Potter may have been a member of the family of E. Potter, an early settler in Lyle Township.

In Kasson, in 1875, Dr. Turner advertised that he treated chronic diseases, and had cured fourteen patients suffering from asthma. In Minneapolis, in 1882, he soon returned to Kasson, reported that he had a cure for consumption. He was licensed to practice in Minnesota on December 31, 1883, certificate No. 718-3, by exemption. He was a Republican, served twice as health officer in Kasson, and at times presented bills to the county for aid to the poor. He died July 16, 1913 at the Washington State Veterans Home, of which he was resident physician.

Emma Washburn (later Rodgers) was born in Mower County, Minnesota, in 1860. She was graduated in 1887 from the Woman's Medical School of Northwestern University (Woman's Hospital Medical College, or Woman's Medical College), Chicago. This school was closed in 1902. After a year's internship at Northwestern Hospital, Minneapolis, she began the practice of medicine in Blooming Prairie, Steele County (1890-1891). In 1891, she opened an office in Austin, and for many years, it is said, had a good practice. She was licensed as a physician in Minnesota under the Affidavit Law of 1887, and again in 1898.

Dr. Emma Washburn Rodgers, of Austin, was listed in Polk's directory of physicians and surgeons for 1904; in the first edition (1906) of the directory of the American Medical Association her name appeared as Emma W. Rogers, but thereafter the spelling, in different directories, was uniformly "Rodgers." The following notes give an approximation of her movements: From 1910 through 1917 she was in Newport, Washington County, Minnesota; from 1918 through 1927 or later, in White Bear Lake, Ramsey County; in 1929 through 1931, "retired" in Carbondale, Illinois.

Dr. Washburn Rodgers died in Salem, Oregon, on September 13, 1933, in her seventy-fourth year, from cardiorenal-vascular disease.

— **Webber** may have practiced in Adams in 1877. In the atlas of Minnesota, 1874, mentioned previously, H. F. Webber, a patron of the publication, was listed as farmer and physician, in section 26 of Le Roy Township, post office Le Roy, who was born in Germany and had come to the United States in 1866. From about 1866 into 1868, H. WEBER, "German physician" and "hygiestic physician," was in Rochester, Olmsted County; this man subscribed to Power and Thornton's "Civic and Congressional Township Map of Minnesota," published in that period. These notes may all relate to the same practitioner.

John N. Wheat (1818-1903) was the second physician to settle in Austin. He arrived in the city in September, 1856, five months after Dr. Orlenzer Allen had begun practice there. Dr. Wheat, for many years, was a prominent physician and respected citizen of Mower County.

He was born January 16, 1818, at "old" Hadley, Massachusetts. When he was a child, the family moved to St. Albans, Vermont, and later to Cleveland, Ohio, where he attended the public schools. He next spent eight or nine years in Geneva, New York, and returned to Ohio in 1850. It was in this latter period that he became interested in the study of medicine. In 1852, he was graduated from the Homeopathic Medical College of Cleveland. In an early account, it was stated that the professors on the staff had belonged formerly to the "old school" before turning to homeopathic practice, and that consequently their students had the benefit of instruction in both systems of practice. During the course, John N. Wheat specialized in anatomy and surgery, and was elected by his class as a demonstrator in anatomy.

Dr. Wheat practiced in Oberlin, Ohio, until 1856, when he came to Austin, where, with the exception of a few short absences, he spent the remainder of his life. Like most other physicians of the period, he used the newspapers to announce his qualifications to the public. In 1859, having been away from Austin for a time, he published the following card in a local newspaper:

> J. N. WHEAT, M.D. Would respectfully announce to the citizens of Austin and vicinity that he has, after strong solicitation from friends, consented to locate again in Austin where he may be found at all times in readiness to attend to all professional business entrusted to his care. Particular attention paid to OPERATIVE SURGERY and Surgical Diseases, diseases of Women and Children, also especial attention to that most awful of all diseases—cancer. Persons wishing to examine specimens of the lip and breast which have been removed can do so by calling at my place of residence, at the house of Rev. S. Cook, on Water Street, Austin.
>
> J. N. WHEAT, M.D.

In the history of Mower County published in 1884 it was written about Dr. Wheat: "He is a man organized by nature for his profession. . . . He seems to thoroughly understand the human system in all of its fine, complex and intricate parts—in short a real specialist at any and all branches of the medical science. As a practical surgeon there are few who can cope with his skill, as his success in this direction will be attested to by the scores of amputations he has made in Mower County during the past quarter of a century."

Under the Medical Practice Act of Minnesota, Dr. Wheat received state license No. 736 (H) on December 31, 1883.

Dr. Wheat was married twice. His first wife was Matilda Jane Dewitt, whom he married at Geneva, New York, in 1841. She died in Oberlin, Ohio, in 1850. The only child of the marriage was Amelia Jane (1842-1863). His second wife was Julia A. Cook, a daughter of The Rev. Stephen Cook, the first, or at least, an early clergyman in Austin. There were three children of this marriage of whom, in 1884, one was living: Carrie M. Wheat (Bascomb) who was born on December 6, 1856, the first girl child born in Austin. She was married February 13, 1878, to Edwin G. Bascomb, of Rochester, a brother of Dr. Marshall T. Bascomb, who in the late seventies practiced medicine in Brownsdale and in Grand Meadow.

In April, 1882, Dr. and Mrs. Wheat moved to Rochester, where the doctor practiced until March, 1883 when they returned to Austin. A statement sometimes seen, that Dr. Wheat "spent a few years in Fillmore County where he was elected state senator" is erroneous. The reference was to Dr. James Madison Wheat (1825-1910) of Lenora, Fillmore County, from 1856 into 1887.

Dr. John N. Wheat died in Austin July 23, 1903.

It has been suggested that **John I. Wheeler** was a physician in Mower County, but corroborative evidence is lacking. Dr. S. P. Thornhill, about 1870, bought from John I. Wheeler a farm in sections 5 and 6 of Austin Township when Mr. Wheeler was moving into Freeborn County.

Obadiah Wheelock, eclectic physician and surgeon, and a farmer, came with his wife and children to Mower County in 1872 and settled on a farm in the northeast quarter of section 35, Windom Township, near Rose Creek.

Obadiah Wheelock was born in New Haven, Oswego County, New York July 20, 1828. When he was two years old the family moved to Oneida County, New York. He attended district school and, for three and one-half terms, Whitestone Academy. After teaching school, both before he went to the academy and afterward, he began the study of medicine under Dr. J. M. Comings of New York City. His training included attending clinics at Bellevue Hospital and lectures at the Metropolitan Medical College, from which he was graduated in 1862. He first practiced at Port Leyden, Lewis County, New York, where he remained several years.

When Dr. Wheelock came to his farm near Rose Creek, he had owned the land some fourteen years, but it had not been much improved. His first undertaking was to build a house, set out trees, and cultivate the soil, practicing medicine at the same time. He was still in practice in the late eighties, and perhaps later. His name does not appear in the official directory of 1883-1890 of Minnesota physicians.

Obadiah Wheelock was married in 1856 to Celesta S. Seymour, who was born in December, 1827, at Turin, Lewis County, New York. There were six children of the marriage: Robin S., Henry L., Emerson W., Alva S., Charles E., and Phillip. Little information about the family has been available; Alva S. Wheelock spent much of his life in or near Rose Creek.

— **Wilder** came to Grand Meadow in the autumn of 1876, the second practitioner to settle in that village. He was associated with Dr. Samuel M. Jenks, the first physician in Grand Meadow, both in practice and in the drugstore that Dr. Jenks operated. Dr. Wilder, who "was not a regular graduate in his profession," came to Mower County from Wisconsin. In 1878 he removed to Iowa City, Iowa.

Sarah Catherine Wilcox was graduated from the Hahnemann Medical College of Chicago in 1876. She practiced in Austin, Mower County, from 1886 into 1891. Her Minnesota state license, No. 1373 (H), was issued April 26, 1887. In 1892 she left Austin to practice in St. Paul, and in 1896, having married, she removed to Seattle, Washington.

John P. Williams, a graduate of the Chicago Medical College in 1876, in that year spent a few months in Austin. He formerly had practiced in Winona. In the official Minnesota medical directory for 1883-1890 Dr. Williams was listed as in Le Sueur, Le Sueur County. His license to practice in the state was No. 764 (R), dated June 2, 1884.

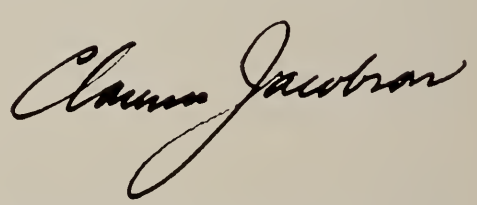
John C. Wysor practiced medicine in Brownsdale from 1878 until 1880, when he returned to his old home in Virginia.

President's Letter

IN APPRECIATION

A year replete with events pertinent to the progress of our profession will soon be history. We have witnessed scientific progress in our medical journals and are continuing to implement the best results by applying them to our daily practice of medicine. The economic aspects have been of great concern and have served to unite us in our efforts to promote legislation which will insure the highest quality of medical care to all the people of our nation.

Visiting various states as your representative was a stimulating experience. I was impressed by the active interest in their scientific programs and the earnest participation of the various Houses of Delegates in their common problems; particularly in the field of voluntary health insurance plans.



In this area, Blue Shield and Blue Cross continue to be the bulwark. Implementation of these plans has not been without problems in some instances. Active participation by the physicians by virtue of having a voice in the selection of members of the corporate structure of Blue Shield appeared to be a source of strength, so necessary in future negotiations.

The past year has given me, as your president, the privilege of representing you on numerous occasions. May I state that the people of our state hold you and our organization in high regard. This image is the result of the splendid work of our local societies. You, as individual doctors of medicine, are to be commended on your continued endeavors to promote good relations with the public by meeting the needs of your patients with a high standard of medical care.

Differences of opinion as to what constitutes the best in medical care and how the demand can be met will call for the ultimate in sound compromise and solution. Our Association has demonstrated its wisdom by placing emphasis upon that which unites us rather than upon what may separate us. Much remains to be done among ourselves as well as with allied agencies and professions to meet the challenges of the future.

My gratitude to the members of the Association for the privilege of representing them, and to the Executive Secretary, Mr. Harold Brunn, and his splendid staff for their cooperation and assistance. All have contributed to make this a truly satisfying year for me.

My best wishes to all for a Joyous Holiday Season!

President, Minnesota State Medical Association

THE SAFE CAR

For over ten years, we have been experimenting with ways to prevent injury to persons in a collision, and much of that time the public has suffered through television showings and newspaper accounts of the tests. People say, "There's that man again!" and quickly turn off their sets.

Ideas or inventions are usually viewed as notions or fads, and are expected by everyone to quit bothering after a short time and pass on. But if these ideas or notions depend upon the public for support, they must overcome the prejudice of originality; to do this, they must appear in a form which will assure understanding: In this discussion the idea of the "safe car" is presented, in the hope that the idea will persist, whatever theatricals the tests may appear to employ, and refinements will follow from these engineering tests.

Everyone is familiar with the problem of transporting eggs. They are now packaged in cardboard or pressed paper holders, with widely separated compartments and with supporting areas touching each egg. However, if the cardboard carton is dropped flat on the floor, the eggs will break; but if the pressed paper holder is dropped in the same manner on the floor, most likely none will break. Thus two things are evident: first, the eggs must be held in place with a large properly constructed contact area; and second, the impact to which they are subjected must be absorbed rather than rebounded. This is what we are trying to do with people in automobiles. These two things, careful holding and proper absorbing, are necessary in order to keep people *safe*.

There is a tremendous incentive to package people in cars this way. According to Cornell University Crash Injury Research reports, more than one-half of the deaths and injuries in automobiles occur at a speed less than 40 miles per hour. This one-half would approximate 18,000 deaths, nearly 60,000 totally incapacitated, and about 1.4 million injured. These numbers are as big as they appear from the newspaper accounts each day. Actually, the human suffering and loss of life resulting from automobile accidents follows cancer and heart disease in extent, and the U. S. Public Health Service has declared automotive casualties to have reached epidemic proportions. Therefore, if people could be protected from injury for speeds up to 40 miles per hour, the lessening of injury and death would reduce the problem by approximately one-half. This result can be accomplished by the proper design of cars, if they are made to absorb the energy of collision up to 40 miles per hour without causing injury to people wearing seat belts.

The accomplishments have been made possible by the use of hydraulic energy-absorbing bumpers in front of the car, which reduce the force of impact below that which has been found by Colonel John Paul Stapp to be safe with seat belts. The actual forces of crash into a rigid barricade, such as a bridge abutment or a concrete wall, or a head-on collision, are within the tolerances which can be survived without injury at 40 miles per hour. For higher speed crashes, the packaging which prevails greatly aids in reducing the extent of injuries. Even seat belts alone are very effective in reducing injury at lower speeds and for roll-overs.

The tests we have been making on cars have been to determine the most effective and economical means of utilizing these findings. We have observed, for instance, that a 17-inch stroke of the hydraulic bumper is adequately effective for absorbing the crash energy. This length of bumper cylinders can be hid under the car in front of the frame without changing the length of present-day cars, or modifying the styling that now prevails.

We have been particularly interested in finding ways of mounting the seat belts to make their support more effective, and to make their use most convenient and comfortable. We are working to measure the body motions on a seat belt, and have advocated a retractable steering wheel and a re-

---

Presented at Methodist Hospital, St. Louis Park (Minneapolis), Minnesota, in the Symposium on Automobile Trauma, November 14, 1959.

The author, Professor James J. Ryan, is Principal Investigator for the Automotive Safety Research Project, University of Minnesota.

cessed dash. Other engineering considerations are being studied, such as a dash-pot damper under the seat and a take-up reel on the belts. It may not be unreasonable to find that the steering wheel, in reality, is a safety surface for a person swinging forward on a seat belt, and it may be advocated that cars have dual steering.

We are trying to understand better that which we already know. The principles of the deceleration of the vehicle and the retardation of the people in the car are well understood, but the application by automobile manufacturers has not received engineering consideration. The word "safety" in car production and selling has taken on questionable status. The public will pay very little more for safety, and the car manufacturers know exactly how little that "little" is. However, the public expects to be protected, and has set up safeguards such as the CAA in aviation, the Pure Food and Drug laws, and other controls to alleviate unreasonable conditions. The Federal Government is the only agency powerful enough to regulate safety into the construction of automobiles, and when the situation becomes sufficiently severe, steps will be taken to correct the deficiency. We hope *you* will participate in this clamor, and that *we* shall know how to build the safer cars.

Mr. Alfred Lowell Mosely, an extremely able psychologist at Harvard University, who is now chief investigator in research of fatal highly collisions (in the Boston area), has described briefly the allied work in this field in a letter to Dr. James L. Morrill, former president of the University of Minnesota, two paragraphs of which follow:

"Professor Ryan's work fits importantly into the larger picture of highway accident research. Professors Severy and Matthewson at the University of California in Los Angeles are doing experimental collisions to learn something of what happens to structures and components of the vehicle, and what collision impacts mean to (simulated) occupants. John Moore and staff at Cornell are making important statistical studies of engineering structures which cause injury to occupants, and the nature and extent of the injuries observed. Professor McDermott at Cornell Medical College is studying the management of the injured traveler from the time of injury to the time of discharge from a hospital. Professor Evans of the University of Michigan and Professor Lissner of Wayne University are studying the thresholds of injury to skeletal structures and organs of the human body, using advanced experimental techniques. Professor Baker at Northwestern is making detailed qualitative studies on non-fatal accidents. At Harvard, my colleague, Dr. Richard Ford, and I are doing detailed clinical studies on the fatal collisions.

"The automobile industry maintains a distance from most of these studies, and quietly undermines both the chief investigators and their efforts. The medical profession extends every courtesy to the researchers and gives freely of knowledge and clinical skill. The legal profession maintains close contact with the results of the studies in the interest of justice. The U. S. Government assists in money, materials, counsel, and moral support to these various studies.

"In the U. S. House of Representatives, the Roberts' subcommittee stays well informed on the status of the several studies with the plan of substituting legislative procedures where voluntary cooperation fails."

The first order of business in the Senate of the Congress convening in January, 1960, had to do with highway safety. A film, "Automotive Crash Tests with Dummies and People," of our experiments toward injury prevention in crash and their results, was prepared by the Audio-Visual Department of the University of Minnesota for presentation to these interested bodies. It is hoped that steps will be taken to require proper energy absorbers and restraining devices in the manufacture of cars for the future. By this means, all manufacturers will compete on the same basis and safety will have engineering status. After about ten years, all cars will have this safety construction, and, since action is equal to reaction, the old cars would have equivalent benefit in the event of a collision with a new car.

It may be concluded, from an engineering standpoint, that the safe construction of cars is a modern necessity, and the time is coming closer when it will be a reality. It is another focal point of attention in a rapidly changing world.

James J. Ryan, M.M.E.

AMBULATORY MANAGEMENT OF ESSENTIAL HYPERTENSION

During the past decade, the availability of potent antihypertensive agents plus an improved understanding of pathophysiologic mechanisms has enabled the physician to control diastolic hypertension in the majority of instances. In recent years the need for surgical management and rigid dietary control has gradually lessened. On the other hand, the need for a comprehensive working knowledge of pharmacodynamic actions, electrolyte alterations and methods of drug titration has increased correspondingly.

The hypotensive effect of dietary salt restriction has been adequately confirmed; however,

there are few patients who will adhere to these diets for any prolonged interval. Fortunately the recent availability of potent oral natriuretic agents has lessened the requirement for severe dietary salt reduction. In fact, the daily administration of thiazide diuretics allows the hypertensive subject to ingest 3 to 5 grams of salt per day without aggravation of the hypertensive process. There does not appear to be any current advantage for the rice diet, as recommended by Kempner.

Weight reduction in the obese patient and the administration of sedatives or tranquilizers to the emotionally labile subject are generally recommended. Likewise abstinence from smoking is considered beneficial. However, although these general measures may produce a minor antihypertensive effect, they are only minimally effective in patients with severe diastolic blood pressure elevation.

Among the wide variety of potent antihypertensive agents currently available, the most useful compounds are the thiazide derivatives, Rauwolfia alkaloids, hydralizine (Apresoline), guanethidine (Ismelin), and the ganglioplegic drugs. The usefulness of the Veratrum compounds is limited by the high incidence of associated side reactions, especially nausea and vomiting. Likewise the development of tolerance limits the clinical application of the oral adrenergic blocking compounds.

The various thiazide derivatives possess similar antihypertensive abilities; and when equivalent natriuretic dosages are administered, equivalent hypotensive responses are obtained. The administration of daily dosages greater than 1000 mg. of cholorothiazide (Diuril, or its equivalent) does not produce an additional antihypertensive effect. On the contrary, larger dosages may cause severe untoward electrolyte effects, particularly hypokalemia. Hyperuricemia may also appear secondary to decreased uric acid clearance. When clinical gout occurs, discontinuation of the drug and/or colcichine administration will adequately terminate the attack.

Recent investigative studies indicate that the antihypertensive effectiveness of the Rauwolfia alkaloids is due primarily to its peripheral effect on the postganglionic sympathetic fibers. The Rauwolfia compounds cause an exaggerated release of norepinephrine from the peripheral nerve endings, and the subsequent catecholamine depletion reduces the arteriolar response to sympathetic stimulation. The central actions of these drugs are probably responsible for only minor antihypertensive effects.

Guanethidine and the ganglioplegic drugs are equally potent hypotensive agents; however, the lesser incidence of side reactions, lack of parasympatholytic effects, and prolonged therapeutic response constitute significant therapeutic advantages for the newer agent.

Despite the availability of numerous effective agents, the search continues for more potent antihypertensive compounds. The employment of various enzyme inhibitors is currently under investigation. It has been demonstrated that the monoamine oxidase inhibitors, including iproniazid and nialamide, possess significant orthostatic hypotensive effectiveness when administered in large dosages. Although the precise mode of action remains uncertain, the activity of the MAO inhibitors appears due (at least in part) to ganglionic blockade. The decarboxylase inhibitors likewise show potential clinical usefulness. Decarboxylase inhibition depresses the biosynthesis of norepinephrine, and a consequent hypotensive effect ensues.

The need for sympathetectomy and/or adrenalectomy has been drastically reduced during recent years. At present, the overwhelming majority of hypertensive subjects can be adequately controlled by medical means. Those patients who fail to respond are candidates for surgical therapy; however, less than 5 per cent of hypertensive subjects fall into the latter category.

Within the past year, an extensive statistical analysis of blood pressure levels and subsequent clinical course in young hypertensives has been reported. The data obtained offers a revealing analysis of the natural history of hypertension and indicates an unequivocal increase in morbidity and mortality rates in these subjects. Perhaps most important of all was the finding that patients with mild diastolic pressure elevation (90-100 mm. Hg.) had a significantly increased incidence of cardiovascular complications, as compared with their normotensive counterparts. These findings coupled with increasing evidences that vascular deterioration can be halted or reduced by effective antihypertensive treatment confirms the need for a dynamic approach to the management of the hypertensive subject.

Minnesota State Medical Association
George Earl, M.D., Chairman

AMA PRESIDENT REFUTES CRITICS AT SAINT PAUL LUNCHEON

Dr. E. Vincent Askey, Los Angeles, President of the American Medical Association, told a meeting of the St. Paul Area Chamber of Commerce at the St. Paul Hotel on October 26, 1960, that one of the most frequently heard criticisms is that the AMA restricts the number of medical students.

"Our Association does not regulate the number of students admitted to medical schools. It does not decide whether new schools are to be built; it does not decide whether schools are to be expanded," Dr. Askey said.

"Our concern at the moment is that there are not enough medical students being trained for a great profession and that there are not enough talented applicants to medical schools.

"The American Medical Association wants to increase the number of doctors, not limit it," he said.

Refutes "Against Everything" Myth

He also took issue with another popular myth by pointing out that "the American Medical Association is not a negative, 'against everything' organization."

He cited the AMA record concerning legislation in the last Congress. "Our Association testified or submitted statements on forty occasions concerning twenty-five bills," he said. "In twenty-six instances our position was favorable to the legislation under consideration, and eight times we offered our views in an informational manner, expressing our opinion on broad, general subjects rather than on specific proposals.

"Only six times were we opposed to proposed legislation or provisions in a bill," he said.

Dr. Askey added that on the most important issue, "medical care for the aged—we supported a broad proposal of federal-state matching funds to provide care for the needy and near-needy aged without a compulsory system of taxes and coverage-for-all under Social Security."

Dr. Askey noted that "the American Medical Association is desperately concerned about all our elderly citizens, especially their health, their medical needs and their happiness.

"This concern has been twisted and distorted badly by some. To listen to them you get the impression that the AMA and physicians are encouraging the death and suffering of thousands and that we favor a minimum of medical care or none at all, for the elderly.

"I assure you, and all Americans in the older age group, that never were more physicians more sincerely dedicated to the promotion of good health among the elderly and more concerned about delivering the best medical care and services to all these persons," said Dr. Askey.

Need for Mills-Kerr Bill Stated

"Naturally, we in the medical profession were delighted that the House and Senate favored the Mills-Kerr proposal, which we supported, over the compulsory-type measures. We were gratified that the President signed it into law.

"We know that there are older people in this country whose need is great, whose need is immediate. That is why we supported wholeheartedly the Mills-Kerr bill.

"We want the new law to help those on Old Age Assistance, and the undetermined number of people who, while able to pay the other costs of living, find it difficult to withstand the additional burden of the cost of illness.

"These are the people who need help. These are the people who must be helped through the Mills-Kerr bill.

"In the process of helping them, we are preserving voluntaryism . . . we are following the traditional federal-state organizational structure of our nation's government . . . we are maintaining local autonomy . . . we are practicing true economy and avoiding fiscal irresponsibility . . . and we are preserving the right of self-reliant individuals to finance their own health care, as they are doing now and doing satisfactorily," said Dr. Askey.

"It should be clear to any objective person that

government's responsibility is to help those who need help, and that the government's responsibility goes no further.

"When the government does for its citizens the things that they have *the capacity to do for themselves,* our free nation shall be in serious trouble," he emphasized.

Opponents Want Mills-Kerr Bill Failure

Doctor Askey warned that "at the moment, however, there seems to be a conspiracy to prevent the new joint federal-state medical care program for the aged from going into effect around the nation. Those favoring the Social Security approach would have states believe that the development of the Mills-Kerr bill at the state level is too difficult and too confused. Their object obviously is to keep as many states as possible from adopting legislation implementing the new legislation passed by Congress and signed into law by President Eisenhower."

He urged that "as backers of this voluntary, federal-state matching grant program, all of us must do everything possible to see that all states participate." He pointed out to the luncheon guests that several states already have joined the program. In adopting regulations for eligibility and benefits, these first states apparently were neither confused nor slowed by so-called difficulties or ambiguities in the new law.

"I want to assure you that we in the American Medical Association shall do everything possible to encourage states to participate."

Doctor Askey noted that recently the AMA has issued a joint statement with the American Hospital Association urging the early adoption of implementation legislation in every state.

"Having gained this Mills-Kerr victory, we must not become apathetic and forget the follow-up or leave the details to others. We must do what we can to see that all the needy and near-needy aged receive the medical help they have coming under the new law."

HEALTH INSURANCE POLICYHOLDERS IN MINNESOTA REACH NEW HIGH

The number of persons in Minnesota with health insurance reached a new high of 2,681,000 at the end of 1959 reports the Health Insurance Institute.

The report was based on the 14th Annual Health Insurance Council survey of health insurance coverage in the United States, which revealed that nearly 128 million Americans, or 72 per cent of the total civilian population, were protected by health insurance as of December 31, 1959.

The survey of reports from insurance companies, Blue Cross-Blue Shield and other health care plans, disclosed that the number of persons in the state with hospital expense insurance increased by 38,000 during the year to reach a total of 2,681,-000 at the end of 1959.

The number of persons with surgical expense insurance climbed from 2,455,000 at the end of 1958 to 2,525,000 at the end of last year. Persons protected by regular medical expense insurance, which helps pay for doctor visits for non-surgical care, increased from 1,769,000 to 1,881,000.

DOCTORS ASKED TO PRESCRIBE CHEAPER DRUGS TO WELFARE PATIENTS

Physicians in Philadelphia have been asked by William B. Tollen, Commissioner of Public Assistance in the Pennsylvania State Department of Public Welfare, to prescribe less expensive drugs for patients receiving public assistance.

His request came in a letter published in *Philadelphia Medicine,* the journal of the Philadelphia County Medical Society. Tollen asked his readers to become "cost conscious" when prescribing drugs under those programs.

"We recognize that your primary concern as a practitioner," he said, "is to see that the patient receives adequate care. As a member of the community and a taxpayer, however, you are undoubtedly also concerned with the economical use of public funds."

Tollen said expenditures for drugs are running out of proportion for all other items of medical care. He said total expenditures for medical care in 1949 were $4.7 million. Ten years later, he said, they were $8.7 million. Expenditures for drugs in 1949 totaled $1.5 million, or 32 per cent of the total. In 1959, drug expenditures were $4.7 million, or 54 per cent of the total.

"This is a matter of deep concern to the department," Tollen said, "particularly at a time when an impending deficit in our appropriation creates an urgent need to conserve funds. Frankly, we are appealing to you to become 'cost conscious' when you prescribe under our program. We are asking that you exercise careful consideration and professional discretion in choosing medication."

INTEREST IN "COST OF DRUGS" INSURANCE GROWS

Health insurance coverage against the costs of drugs has been steadily expanding, but the eventual role which insurance or prepayment might play in this field is not yet resolved, according to J. F. Follmann, Jr., Director of Information and Research, Health Insurance Association of America.

In an 88-page study dealing with "Drugs, Their Cost, and Health Insurance," Mr. Follmann reported:

"Today there is an increasing degree of insurance of prepayment for the costs of drugs. As voluntary health insurance mechanisms developed protection against the costs of hospitalization some twenty-five to thirty years ago, the costs of drugs prescribed in the hospital were automatically included in the coverage. At that time, however, there was little coverage available for out-of-hospital drugs.

Ten-Year Growth in Medical Expense Insurance Cited

"With the development of major medical expense insurance by the insurance companies about a decade ago and the development of extended benefit coverages by the Blue Cross-Blue Shield plans, an increasing amount of health insurance has become available against the costs of out-of-hospital prescription of drugs."

He said the extent of protection against the costs of prescription drugs was not known, but noted that more than 22,000,000 Americans now have major medical coverage.

Mr. Follmann stated:

"The combined circumstances of improved effectiveness of drugs, increased utilization of drugs, rising cost of drugs, and a willingness on the part of the consumer to spend an increased portion of income, has resulted in increased personal and family expenditures for drugs, both directly and through health insurance and prepayment plans.

Drugs Important Factor in Medical Care Cost

"This can produce a situation of consequence to health insurers and to the purchasers of health insurance, since drugs can become an increasing factor in the costs of medical care and hence in the premium for protection against these costs.

"This, in turn, points to the need for health insurers to give specific consideration to the inclusion of drug costs in their coverages to the extent necessary to and desired by the public, and in such form as to produce the most efficacious results . . ."

The HIAA official said there was growing recognition in the insurance business of the need for more definitive data and knowledge with respect to the financing of drug costs. More experience by insurers, both in breadth and depth, is needed to help determine the role which insurance or prepayment should play in offering protection against such costs, he indicated.

Doctors Play Key Role

Noting that doctors play the key role in the use of drugs, and consequently in the cost of drug coverages, Mr. Follmann emphasized that the most efficient and effective use of funds allocated for drug and other health cost insurance would require "the full and active cooperation of the providers of care . . ."

He also called for "the education of pharmacists" on the nature of insurance coverage and the purpose of health insurance.

COURT SAYS MEDICAL SOCIETY CAN DENY MEMBERSHIP TO A PHYSICIAN

The courts have refused to compel a county medical society to accept a physician as a member. On August 29, 1960, a Superior Court Judge in Phoenix, Arizona, ruled that the courts cannot compel the Maricopa County Medical Society in Phoenix to accept a doctor as a member. The judge said that the medical society is a private corporation and membership in the society may not be acquired as a matter of right and may be denied arbitrarily.

SURVEY SHOWS FREQUENCY OF PUBLIC'S VISITS TO DOCTORS

During the two-year period ending June 30, 1959, Americans averaged ten visits to physicians (the figure was based on the rate of 851.6 million visits per year).

The findings of a survey conducted between July 1957 and June 1959 in an estimated 73,000 households covering 235,000 individuals showed that two out of three took place in the doctor's office, 20 per cent were divided fairly equally between home and hospital clinic outpatient visits, and most of the remainder were in nature of "telephone visits." Urban dwellers used doctors more often than did their country cousins, women more than men, whites more than non-whites.

Editor

NEED FOR MORE DOCTORS

Physicians, medical societies and counsellors in high schools and colleges must step up their recruitment of students for medical schools to assure an adequate, future supply of doctors.

This suggestion was made at a session on doctor supply at the AMA's 1960 PR Institute, devoted to this topic. Other suggestions included:

1. *Medical practitioners* now are not recruiting students for medicine. Individually, they must seek out talented young men and women and sell them on the opportunities in medicine. They must overcome the erroneous belief among students that it is impossible to get a seat in a medical school. They also must inform students that there are tremendous intellectual challenges in medicine and that there are new ways to help students finance their costly medical training.

2. *Medical societies* are promoting recruitment programs, but new projects should be developed. In addition to encouraging their own members to recruit students, medical societies can establish loan funds for needy medical students. And they can work for the removal of state restrictions on medical students from other states.

3. *Counsellors* should be urged to promote a "pre-pre-med" course in high school. The creation of student interest will do much to ease the shortage of talented students for medicine.

Mr. William Just of the Chicago Public Schools urged the medical societies to contact all counsellors in their area, to provide medical career teams to visit high schools, to invite graduating seniors to medical school and hospital open houses, and to emphasize to students the technical aspects of medicine.

He also said that in Chicago the high schools are launching an accelerated program for talented students and that this project may yield a sizable crop of candidates for medical schools.

Attempts to Limit Physician Supplies Denied

Dean Richard Young, M.D., of Northwestern University School of Medicine and Secretary of the Association of American Medical Colleges, emphasized that neither the AAMC nor the AMA has ever sought to limit the output of physicians. In fact, these organizations feel that the most important responsibility and program facing medical education is the recruitment and selection of medical students.

In six years, he said, the number of applicants has dropped from almost 25,000 in 1954 for the 7,000 seats available to 15,000 in 1960 for 8,500 places. Not only is the quantity down, but also the quality, he said.

He called for elimination of the myth about "not getting into medical school," urged the building of student interest in medicine in high school, and stressed the need of more fellowships for medical students to ease their financial burden.

Physician Recruitment Is Important Public Relations Project

C. Lincoln Williston, Executive Secretary of the Texas Medical Association, said that recruitment and doctor supply and distribution is one of the most important public relations projects of medical societies.

He said that medical societies must provide leadership in getting more medical schools, more students, a good supply of physicians for the future, the best possible distribution of physicians and the financial assistance to needy medical students. All of these projects, he emphasized, will bring large public relations dividends to the local society and to its members, in addition to meeting the specific problems.

Dean John Z. Bowers, M.D., of the University of Wisconsin Medical School, asked for the best communications among medical schools, the medical profession and student counsellors. Unless there is good co-operation, he warned, the problems will get worse and federal control of medical education may be possible.

Mr. Leo E. Brown explained that current AMA recruitment efforts include the sending of medical career kits to 8,000 student counsellors in the nation.

"I AM A DOCTOR"

This AMA film is a dramatic and inspiring survey of the variety of careers now available to every qualified student—in general practice, specialization, research, teaching, and administration. But "I Am A Doctor" is much more—it is a moving, true story of a young physician, who, shortly before his death from leukemia, reflected on the great satisfactions—and sacrifices—which medicine had brought to his life.

Through various camera devices, his thoughts and words are visualized on the screen—the long years of college and medical study, the miracles in surgical amphitheatres, the challenges and frustrations of laboratory research, the joys of bringing hope and recovery to the ill, and the molding of young minds and intellects in the classroom.

The young doctor then projects his thoughts into the future, envisioning the promise of tomorrow—space medicine, applying the atom to medical advances, and the new break-throughs in the conquest of disease.

The total impact of this motion picture leaves little doubt that anyone would be proud to say: "I Am A Doctor."

This 25 mm colored film, especially recommended for guidance programs, careers days, school assemblies and health fairs, is available on a free loan-on-request basis (return shipping charges only) from the AMA Film Library, 535 North Dearborn Street, Chicago 10, Illinois.

MINNESOTA MEDICAL CAREERS RECRUITMENT ACTIVITIES LISTED

In Minnesota, more than 11,000 packets of medical careers materials have been distributed to public and private high school libraries, high school counsellors, and public libraries. The project was coordinated by the Minnesota Commission for Patient Care. The Minnesota State Medical Association is a member of that group. Members of the Woman's Auxiliary were responsible for the distribution of these medical careers packets throughout the state of Minnesota. Included in the packet was the AMA booklet, "Medicine As A Career."

A number of county medical auxiliaries have extended their activities to include periodic visits to libraries and careers counsellors to replenish supplies of medical careers recruitment materials.

AMA MEDICAL CAREERS KITS AVAILABLE

The American Medical Association and the Association of American Medical Colleges have prepared a kit of medical careers programs for high schools, colleges and communities.

This kit is for your use, and the materials—handbooks, pamphlets, exhibits and motion pictures—are available to you without charge. A similar kit has already been sent to all state and county medical societies and their executive secretaries and officers will be happy to cooperate in every possible way by providing speakers, programs and whatever assistance you may require in developing school, college and community programs. Kit materials are available from the State Office.

This kit has also been sent to all medical school deans, state vocational guidance directors, and to all members of the American College Personnel Association, the American School Counsellor Association, and the National Vocational Guidance Association. However, there are undoubtedly a great number of schools in which this program has not yet been introduced, and we would appreciate your using these medical career informational aids whenever possible.

Minnesota Blue Shield

During the first nine months of 1960, Minnesota Blue Shield payments for medical, surgical and obstetrical services of subscribers totaled $7,249,065.39.

This represented 346,229 different services by doctors during the nine-month period.

Of the total payments, $4,851,424.28 were for Plan A contract subscribers, $1,336,678.13 for Plan B subscribers, and $1,061,124.68 for special contracts.

The payments for the first nine months of 1960 were somewhat lower than payments made during the comparable period of 1959, which totaled $7,605,350.45. However, the 1959 figure represented only 290,077 doctor services, compared with the 346,229 services in the 1960 period.

The average fee per service in the 1960 period was $20.93, compared with the average fee during the same months in 1959 of $26.22.

Noteworthy in the report was the high number of diagnostic benefits paid for, including 50,507 diagnostic X-rays and 72,579 diagnostic laboratory services, during the first nine months of 1960.

In addition, there were 8,355 therapeutic X-rays administered and 50 isotope treatments.

In a break-down of other services covered by Blue Shield payments during the first nine months of 1959, there were:

Surgical care of bones, joints and tendons, 17,233 cases; suture of wounds, 9,759; other skin surgery, 40,717; ear, nose and throat surgery, 3,853; tonsillectomies, 5,005; appendectomies, 1,600; neuro-surgery, 2,317; cardiovascular surgery, 1,393; ophthalmology, 3,531; thyroidectomies, 386; thoracic surgery, 369; breast, 1,252; gastro-intestinal, 1,076; herniotomies, 2,093; biliary tract, 1,474; proctology, 2,291; urology, 2,407; gynecology, 8,983; and endoscopic procedures, 6,849.

During the same period, there were 17,174 cases of obstetrical care.

* * *

As a service to the medical profession, Minnesota Blue Shield is naturally dedicated to the principle that the best medicine is preventive medicine.

In keeping with this philosophy, Minnesota Blue Shield in October, 1959, introduced benefits for diagnostic X-ray and laboratory services, when performed in the doctor's office, the patient's home, or the out-patient department of a hospital.

These benefits represent an important contribution to preventive medicine, since they encourage patients to seek earlier diagnosis.

Blue Shield experience during the first year of this new program indicates that subscribers are making extensive use of this coverage. During the first nine months of 1960, 50,507 diagnostic X-rays and 72,579 diagnostic laboratory services were provided under this program.

Dr. Richard R. Cranmer, executive director of Minnesota Blue Shield, noted, "The diagnostic benefits of Blue Shield coverage can have far-reaching effects for the public health of this state, since early diagnosis can often help prevent more serious conditions from developing."

He added, "It is hoped that many more subscribers, during the months ahead, will take advantage of these benefits to help them stay well and help them stay out of the hospital."

Patients, of course, need to be educated to make use of this medical care feature. Doctors should do all they can to impress upon their patients the importance of this Blue Shield benefit and urge them to make full use of it.

This task of public education is required because, far too often, today's patient regards his hospitalization coverage as the means whereby he can receive such diagnostic services. Often, the patient will postpone seeing his doctor until hospitalization may be required merely because he believes only his hospitalization coverage will protect him for such services.

This overemphasis on hospitalization coverage is seen in the fact that many persons use the term "hospitalization" to mean health-care insurance in general, as if it were the all-embracing term which includes hospital care as one of the ancillary services of the doctor of medicine.

That medical care is underemphasized is illustrated by the fact that a high percentage of those who carry hospitalization coverage of some kind do not carry medical-care coverage.

A more proper perspective toward health-care can be gained through education with the stress placed on preventive medicine.

Medical Education

MEDICAL PROGRESS MAKES CAREER OF PHYSICIAN MORE ATTRACTIVE

Medicine today offers more opportunities and rewards than ever before but there are signs that many young persons are failing to take advantage of them, noted a special report released by the AMA.

While the number of students entering the profession is increasing, the number applying for admission to the nation's eighty-five medical colleges is decreasing.

Since 1956, the number of applicants has dropped steadily from 15,917 to 14,951. In 1947, nearly 7 per cent of all college graduates made applications for medical schools. In 1958, only 4 per cent applied.

The Minnesota Picture

Dr. Robert B. Howard, Dean of the University of Minnesota Medical School, reporting to the 1960 House of Delegates, presented the following facts about medical education in Minnesota.

"In Minnesota—after a low point of 282 applicants for our then 125 places—we have now come up a little, and our picture is looking a little better. Last year, for example, we had 337 applicants for an increased number of places, 140 places, and our ratio is 2.4 applicants for every place. Our situation is like that of other state supported medical schools. State supported schools, in general, have much smaller numbers of applicants than the private schools, because the state schools do have to take into account geographic factors in making their selections. I mentioned the fact that we have gone to 140 students. We are planning, contingent upon adequate financial support as provided by the next Legislature, to go to 150 students to be admitted. This even in the face of the situation I have outlined with regard to applicants."

Some of the reasons behind the figures are known. The low birth rates of the '30s undoubtedly are partly responsible for the decrease in applicants in recent years. Multiplying opportunities in other fields also are believed to be diverting possible medical candidates.

The AMA article comments that those who pass up medicine today are doing so at a time when it has become one of the most rapidly progressing fields in the nation offering maximum promise for a young man or woman.

Medical Research Grows

The rate of progress is reflected in the huge growth of medical research. In 1940, medical research amounted to $45,000,000. This year it will reach roughly $600,000,000 and predictions for 1970 go as high as $3,000,000,000.

Obviously, a greater number of researchers are needed now than before and will be needed in ever increasing numbers in the future. The expansion is sure to continue because each discovery inevitably opens up new avenues of investigation.

Space Age Medicine Offers New Challenge

Some opportunities created in medicine by recent developments, such as the dawn of the space age, are well known. But there are equally as many opportunities in other areas of medicine not so well known.

For example, medical scientists have become increasingly aware of the fact that the total health of a person depends on the health of each individual cell of his body. This has led to an intensified study of the chemical and physical nature of the cell calling for researchers whose primary interest is chemistry and physics. It may be the work of the biochemist and bio-physicist on the cell that holds the key to heart disease, cancer and mental illness.

Every branch of science plays a role in medicine. Mathematics, for one, has important applications. On the surface, biology appears to be a disorderly process. But if living organisms follow the pattern found elsewhere in nature, there must be laws governing their behavior. The unique challenge of medicine to the mathematician is to find these laws that will bring order out of disorder.

Medicine offers a never-ending challenge to the inquiring mind. Although many diseases have been conquered, many more remain unsolved. Despite the rapid accumulation of knowledge, there is so much left to be learned that this is probably only the first act of the show.

At the same time medical progress is opening up new opportunities for young physicians, the population explosion and rising standard of living,

are increasing opportunities by increasing the demand for medical service.

More Medical Specialists Needed

There is a greater need for physicians in every one of the profession's 50 specialities and subspecialties. Regardless of the area he chooses, the young M.D. can be assured of filling a real need and performing a valuable service.

Average Student Could Study Medicine

Some prospective candidates for medical school may not apply in the belief that medicine is too difficult a field for them. Actually, the study of medicine is within the grasp of the average student. Few college students who make a serious effort could not graduate from medical school.

Before anyone decides medicine is too difficult for him, he should remember that physicians are made, not born. They are human beings like other human beings, and the esteem they eventually earn results from training and experience.

A typical group of medical students represents a variety of talents and interests. Most are "B" students with a well-rounded background in the sciences and humanities.

The chances of being admitted to medical school were never brighter. Educational facilities are being continuously improved and expanded. Nine new medical schools have been created since the end of World War II.

Consequently, more applicants can be accepted and the number of students enrolled has shown a steady increase. This in turn has produced more graduate M.D.s in the postwar period.

Curriculums Are Streamlined

Also encouraging are the efforts now under way to shorten the total span of formal education in medicine. These include the move to combine college and medical school into a single program leading to the M.D. in six or seven years. Doctor Howard told delegates that curriculum changes are also underway in Minnesota.

Financial Need of Medical Student Told

At the same session of the Minnesota State Medical Association House of Delegates, Doctor Howard commented on the need for loan funds for medical students.

"We do have need for loans. First, I want to say something about the short term loan program. A year ago your society very generously authorized a short term loan program. You provided $2,000 for the Medical School, and operated this through the Minnesota Medical Foundation, for the purpose of helping the student who acutely needs money. He's got to pay his tuition, or he's got to pay the rent. He's got to buy groceries, or he needs money for a couple of weeks until his ship comes in, or maybe for a month until he can float a more permanent type of loan. We knew there was such a need."

Doctor Howard pointed out that the $2,000 loan fund set up by the Minnesota State Medical Association was turned over one and one-half times during the first eight months of its existence.

"This has been a very active loan fund, and very useful—and there have been no defaults. The maximum amount of time for this loan is three months, and there is no interest. After this, the student has to get a more permanent type of loan.

"Now our students have need for longer term loans—and maybe we should include the faculty in on this too, I don't know. But the students have need for longer term loans. We have a University program of loans operated through the University's Bureau of Loans and Scholarships. These funds are used, and used quite extensively. However, they have very definite limitations, and these limitations do work hardships on medical students. They have a maximum annual borrowing allowance of $750 and a total of $1500. In other words, all that a medical student can borrow during his entire four years from the University's Bureau of Loans and Scholarships is a total of $1500. And we do have some very serious needs for additional funds, funds which could be made available to students over and beyond these limited funds."

New Loan Fund Established

A new permanent loan fund for medical students at the University of Minnesota was established by the House of Delegates. On recommendation of the Council, approximately $13,000 was appropriated by the delegates for this fund and it will be available at low interest rates for students who have exhausted all of the loan possibilities made available to them through other sources and who might otherwise be obliged to abandon their careers in medicine.

At the same time, final details were agreed upon for an emergency loan fund to be called the "Herman M. Johnson Emergency Student Loan Fund" which will be used for short term loans to tide medical students over financial crises. It will be available in amounts up to $200 without interest for periods of ninety days. A total of $4,000 has been appropriated for this fund of which $3,100 is a transfer of the Herman M. Johnson Fund held by the Association for many years. It

is to be used for an appropriate memorial to the late Dr. Herman M. Johnson of Dawson. Doctor Johnson was a University Medical School graduate, a former president of the Association and first chairman of the Committee on Public Health Education.

Move to Establish New Medical School in Minnesota

A resolution passed by the House of Delegates approved the establishment of a new medical school in Minnesota. The resolution further stated that the Minnesota State Medical Association cooperate with a well-organized effort to establish a new medical school in Minnesota.

Saint Paul Seen as Location for New Medical School

The Northern Association for Medical Education was organized by seventy-one physicians in the fall of 1958. This group saw the impending shortage of physicians that faced the nation in the next twenty years and felt the imperative need to take action.

The announcement of their intentions brought in other members until the organization grew, within a few months, to more than 248 doctors.

During the first year NAME developed its program through committees: to incorporate as a nonprofit organization; to establish relations with educational institutions; to formulate the definition of its objectives in terms of a medical school; to create interest from civic and governmental bodies, and to document the reasons why Saint Paul was a logical place to build a new school of medicine.

In 1960, NAME set up offices and retained an experienced administrator in the field of medical education. NAME is now in the development period, striving to work out a detailed program.

In Memoriam

ARTHUR J. HENDERSON

Dr. Arthur J. Henderson, Ramsey County coroner, died October 21, 1960, in St. John's Hospital in St. Paul.

Doctor Henderson, sixty-six years of age, was appointed coroner in 1955 on the retirement of Dr. Carl Ingerson. He was a deputy coroner for a decade before that. He was re-elected to a four-year term in 1958.

Doctor Henderson introduced two innovations as coroner: a fingerprint bureau in 1957 and a short "coroner's school" for suburban police in September of this year.

He was born in Lake Mills, Iowa, where he received his preliminary education. He attended St. Olaf College in Northfield, Minnesota, where he received his Bachelor of Arts Degree in 1915. His medical degree was obtained from the University of Illinois College of Medicine in 1919.

Doctor Henderson practiced medicine in Kiester, Minnesota, from 1920 to 1944 and then moved to St. Paul in 1945. He was a public health officer and public school physician in North St. Paul, where he also maintained a private practice.

He was a member of the Masonic Lodge, Ramsey County Medical Society, the Minnesota State Medical Association, and the American Medical Association.

Survivors include his wife, Hazel; a daughter, Mrs. Wayne Hurd, Dallas, Texas; two sons, Arthur A., U. S. National Parks Service, Asheville, N. C., and Lowell A., St. Paul, and two grandchildren.

Another son, Edwin, a pilot with Capital Airlines, died in a plane crash in 1958.

DANIEL F. PENNIE

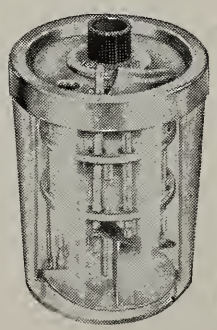
Dr. Daniel F. Pennie, retired Duluth physician, died October 3, 1960, in a Duluth Hospital. He was seventy-nine years of age at the time of his death.

Doctor Pennie was born in Villard, Minnesota, and received his preliminary education at Alexandria, Minnesota. He attended Carleton College in Northfield, Minnesota, from which he received a Bachelor of Science degree in 1909. He taught high school in Stillwater for a year before entering the University of Minnesota Medical School. He received his medical degree from that school in 1914.

After practicing medicine in the state of Washington and in Northfield, Minnesota, he moved to Duluth in 1916 and was associated there with the late Dr. Robert Graham.

During the forest fire of 1917, he headed the medical staff of the Home Guards. After resigning from that post, he headed the medical department at the Butler Shipyards in Superior. He retired from active practice in 1955.

Doctor Pennie was a member of the Ionic Lodge, AF & AM; Scottish Rite Bodies, Aad-Temple of the Shrine, St. Louis County Medical Society and American Medical Association. He was granted life membership in the Minnesota State Medical Association in 1955.



Surviving are his wife, Florence; a daughter, Mrs. Bernard Ostendorf, Stanford, Connecticut; two sons, Donald, Minneapolis, and Robert, Duluth; two sisters, Mrs. E. Garrett Clarke and Mrs. Robert Ballentine, Villard, and eight grandchildren.

Wesson is poly-unsaturated . . . never hydrogenated

More acceptable to patients. Wesson is preferred for its supreme delicacy of flavor, increasing the palatability of food without adding flavor of its own.

Uniformity you can depend on. Wesson has a poly-unsaturated content better than 50%. Only the lightest cottonseed oils of high iodine number are selected for Wesson, and no significant variations are permitted in the 22 exacting specifications required before bottling.

Economy. Wesson is consistently priced lower than the next largest seller.

leans 12, La.

WESSON'S IMPORTANT CONSTITUENTS

Wesson is 100% cottonseed oil...winterized and of selected quality

Linoleic acid glycerides (poly-unsaturated)	50-55%
Oleic acid glycerides (mono-unsaturated	16-20%
Total unsaturated	70-75%
Palmitic, stearic and myristic glycerides (saturated)	25-30%
Phytosterol (Predominantly beta sitosterol)	0.3-0.5%
Total tocopherols	0.09-0.12%

Never hydrogenated—completely salt free

Kills "GOLDEN VILLAIN"
Staphylococcus aureus in
30 SECONDS

Protects Gives bacteriostatic protection for days due to its residual effect

Deodorizes within seconds

here's how Pheneen® Solution plays "Beat the *Clock*"

Recent tests have shown that Pheneen Solution uniformly kills virulent cultures of Staphylococcus aureus within 30 seconds after contact.[1] Other tests against a wide variety of pathogenic bacteria, fungi and *spores* prove Pheneen's germicidal superiority in speed and effectiveness. Add to this the economy, lack of irritation and complete instrument protection, and you have the reasons why Pheneen Solutions are winning new users daily.

The active ingredients of Pheneen are not volatile and remain for long periods of time giving prolonged protection as an invisible bacterial barrier.

The deodorizing quality of Pheneen has been utilized for odor control throughout the hospital and professional office. In this respect it is without equal, deodorizing instantly upon contact, yet never leaving an odor of its own.

Pheneen Solution N.R.I. contains No Rust Inhibitors, and is recommended for sterilization of non-metallic objects. Both types are supplied in quart and gallon bottles, and in bulk drums.

NEW ANTI-MALARIA PILL DEVELOPED UNDER ARMY RESEARCH CONTRACT

A new anti-malaria pill which promises to be the most effective anti-malarial drug combination developed so far, soon will be given to U. S. troops in Korea, the Department of the Army announced.

Resulting from Army supported studies conducted by Dr. Alf S. Alving of the University of Chicago, the new tablet combines two drugs used separately in the past for malaria prevention—chloroquine and primaquine, both developed since World War II. Dr. Alving's investigations have been conducted under contract with the Army Medical Research and Development Command, Washington, D. C.

Since 1951, chloroquine and primaquine have complemented each other in malaria treatment although they have not previously been taken together in tablet form. New treatment procedure for military personnel in malarious areas will be the administration of one of the new tablets each week.

Korea is one area where malaria is prevalent and the drug will be used there first. Because it is so easy to administer, the new pill is a great improvement over earlier treatment methods. Standard treatment in recent years has been a weekly dose of chloroquine to suppress typical malaria symptoms—recurring chills and fever—caused by malaria parasites in the blood cells of people bitten by malaria bearing mosquitoes. Upon leaving the malarious area, military personnel took primaquine for fourteen consecutive days. This drug kills malaria parasites which otherwise could dwell for years in the liver and other tissues, causing later relapses of the disease.

Chloroquine, an excellent suppressant but no cure for the disease, is relatively easy to administer. Military personnel have used it in malarious areas since the start of the Korean War in doses of one tablet a week without unpleasant side effects. It has replaced World War II's atabrine and the traditional quinine, both of which had to be taken daily to suppress malaria symptoms. Both tended to produce nausea, headache and other unpleasant effects.

In 1951, primaquine, an actual cure for malaria, was ready for use. It was found it could be used effectively without bad side effects when administered in controlled doses. This treatment usually was accomplished under close supervision of medical officers on ships returning troops from overseas. Because of today's shortened travel time, personnel returning to the United States by fast ship and by aircraft will benefit from elimination of the fourteen-day treatment period.

The new pill has as yet been given no name.

DEPARTMENT OF THE ARMY
Office of the Surgeon General
Technical Liaison Division
Washington 25, D. C.

This Section is for you to voice your convictions, comments, and queries on all subjects political, economic, historic, humorous, scientific or otherwise, to many physicians. Writings not sufficiently formal and too brief for an editorial or a scientific manuscript are requested. Clinical and research observations, no matter how brief, similar to those in *The Lancet* (London), are particularly encouraged.

The Physician's Diary

New officers of the Northern Minnesota Medical Association for the ensuing year are **L. J. Opsahl, M.D.**, Willmar, President; **Ray A. Johnson, M.D.**, Fergus Falls, Vice President; and **Josiah Fuller, M.D.**, Duluth, Secretary-Treasurer. The 1961 annual meeting will be held in Willmar, Minnesota.

* * *

At the recent meeting of the American College of Surgeons, **Walter A. Fansler, M.D.**, Emeritus Professor of Surgery, University of Minnesota, was elected to the Board of Governors of the American College of Surgeons.

* * *

The opening of a physician's office in Savage has been assured with the announcement that **Dr. Eugene Kuz**, Shakopee, will begin practice there. Dr. Kuz has been associated with **Dr. Bror Pearson** in Shakopee since July. He received his degree in medicine from National University of Ireland in Dublin.

* * *

Three Mayo Clinic staff members attended the 22nd annual meeting of the American Academy of Neurological Surgery in Boston and participated in the program. **Dr. George S. Baker** presided at the meeting as president and delivered the presidential address on "The Generations of Neurosurgeons: Past, Present and Future." **Dr. John W. Kirklin** and **Dr. Alfred Uihlein** both presented papers.

* * *

Dr. W. V. Knoll, Brainerd pathologist, addressed the St. Joseph's Hospital professional staff nurses at their monthly meeting. Doctor Knoll lectured on laboratory tests and their role in diagnosis and treatment.

* * *

Mayo Clinic surgeon, **Dr. W. H. ReMine**, received the motion picture award of the American College of Surgeons at the meeting in San Francisco. The award was for the film entitled "Branchial-Cleft Cysts and Sinuses: Their Embryologic Development and Surgical Management," which was presented at the 1959 meeting of that Association.

* * *

Dr. Arthur C. Kerkhof, Minneapolis, addressed the semi-annual meeting of the Minnesota Society of Internal Medicine at St. Luke's Hospital in Duluth. Dr. Kerkhof spoke on rehabilitation for cardiac victims.

* * *

Newly elected officers of the Mayo Foundation Alumni Association include **Dr. L. Raymond Scherer**, Minneapolis, President and **Dr. Howard Andersen**, Rochester, Secretary-Treasurer. The election took place at the Association's 36th annual meeting in Rochester.

Graceville physician and surgeon, **Dr. I. L. Oliver**, suffered a mild stroke while on his annual goose-hunting trip northwest of The Pas in eastern Saskatchewan. **Dr. Daniel J. Moos**, Minneapolis, took care of the surgery calls during Dr. Oliver's absence.

* * *

Dr. Carl E. Johnson, Rochester, and his wife have returned from a one-month tour of the Scandinavian countries. While there, Dr. Johnson visited medical centers in Malmo, Lund, Uppsala and Stockholm, Sweden. His visit to the Karolinska Institute in Stockholm was of particular interest.

* * *

Sun City, Arizona, is the new home of **Dr. J. J. Heimark**, former Fairmont physician and surgeon, and his wife. Doctor and Mrs. Heimark left Fairmont during the month of October. Dr. Heimark says that Sun City has a center for physicians, surgeons and dentists which attracted him and spurred his decision to locate there. Sun City is a suburb of Phoenix.

* * *

Dr. F. Henry Ellis, Jr., Mayo Clinic, has been appointed assistant editor of the Lewis-Walters "Practice of Surgery" which is published in twelve volumes by W. F. Prior Company, Inc. **Dr. Waltman Walters**, also of the Mayo Clinic, is editor-in-chief of this publication.

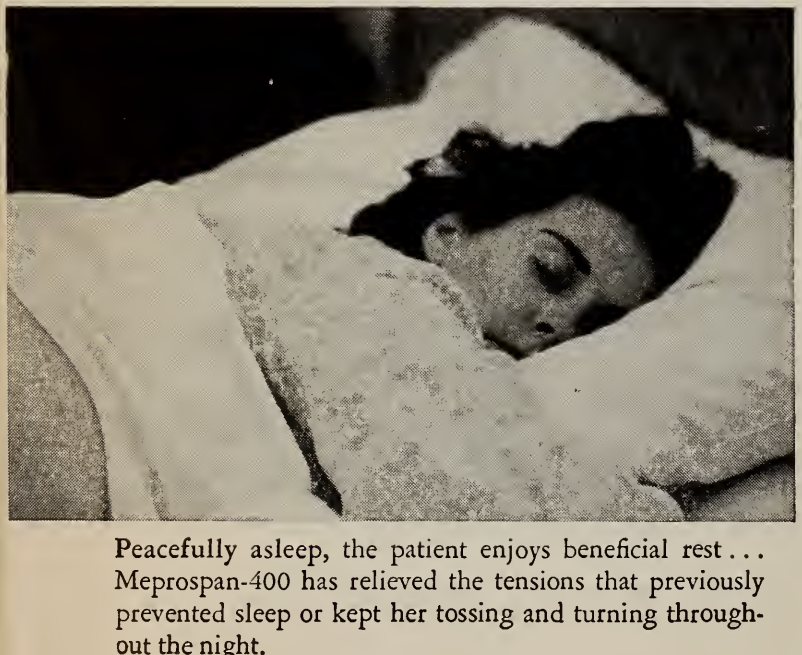
* * *

Two new consultants have been appointed to the Mayo Clinic staff. They are **Dr. Deloran L. Thurber**, Rochester, who received his degree in medicine from the University of Minnesota Medical School, and **Dr. James V. Ross, Jr.**, Easton, Pennsylvania. Doctor Ross graduated from Duke University School of Medicine.

* * *

The Wabasha County Medical Society has elected the following new officers: **Dr. L. M. Ekstrand**, Wabasha, President; **Dr. Wm. P. Gjerde**, Lake City, Vice President, and **Dr. D. G. Mahle**, Plainview, Secretary-Treasurer.

After a history and a physical ruled out organic disease, the physician diagnosed the case as recurring states of anxiety. To relieve these symptoms for this busy, on-the-go housewife, he prescribes Meprospan-400, the *only* meprobamate in *sustained-release* form.



As directed, the patient takes one Meprospan-400 capsule at breakfast. Her symptoms of tension and nervousness are soon relieved, and she will not have to remember to take another capsule until dinnertime.

Calm and relaxed, the patient is no longer upset by the pressures and irritations met in everyday life, nor is she likely to be incapacitated by autonomic disturbances, drowsiness, ataxia or other untoward reactions.

Alert and attentive, the patient participates in a P.T.A. meeting, following her second capsule of Meprospan-400 taken with the evening meal. Meprospan-400 does not decrease her mental efficiency or interfere with her normal activities or behavior.

Peacefully asleep, the patient enjoys beneficial rest . . . Meprospan-400 has relieved the tensions that previously prevented sleep or kept her tossing and turning throughout the night.

most widely prescribed tranquilizer . . .
most convenient dosage form . . .

ONE CAPSULE LASTS 12 HOURS

Meprospan®-400

400 mg. MILTOWN® SUSTAINED-RELEASE CAPSULES

Usual dosage: One capsule at breakfast lasts all day, one capsule with evening meal lasts all night. **Supplied:** Meprospan-400, each blue-topped *sustained-release* capsule contains 400 mg. Miltown. **Also available:** Meprospan-200, each yellow-topped *sustained-release* capsule contains 200 mg. Miltown. **For children:** Capsules can be opened and the coated granules mixed with soft foods or liquids.

Both potencies in bottles of 30.

Samples and literature available on request.

WALLACE LABORATORIES / *Cranbury, N. J.*

Five Rochester surgeons participated in panel discussions during the annual clinical meetings of the American College of Surgeons. They were: **Dr. John M. Waugh,** who moderated a panel during a colectomy: **Dr. Deward O. Ferris,** panelist, during the cholecystectomy; **Dr. Wm. H. ReMine,** panelist, gastrectomy; **Dr. Joseph H. Pratt,** panelist, hysterectomy; and **Dr. Edward S. Judd,** moderator, during a radical neck dissection.

* * *

Dr. L. M. Randall, Mayo Clinic emeritus member, was honored at a dinner by the people who worked with him. A travel fund for clinical trips by residents in his section was set up in his honor.

* * *

The Hawley Chamber of Commerce recently sponsored a banquet in honor of **Dr. V. D. Thysell's** twenty-six years of medical practice in Hawley. The banquet was held at the Hawley Lutheran Church. Dr. Thysell has recently opened a practice in the new Moorhead Medical Center.

* * *

The association of **Dr. Duane L. Orn,** formerly of Turtle Lake, Wisconsin, with the Olmsted Medical Group, has been announced. Dr. Orn will be in general practice. He is a graduate of the University of Minnesota Medical School.

* * *

Effective October 15, of this year, **Dr. Olaf Lukk** began a practice of medicine in Prior Lake, Minnesota. He had formerly been a physician and surgeon in Montgomery for over six years.

Dr. Karl Palmer, an associate with the Oliver Clinic in Graceville since August 1959, has resigned his position there and is now located in Menomonie, Wisconsin, where he has joined a group of physicians in the Red Cedar Clinic. At his new location, he is limiting his practice to the field of internal medicine.

* * *

Dr. E. F. Gambill, Rochester physician, has returned from a trip to South America. He presented a paper at the 7th Pan-American Congress of Gastroenterology held at San Diego and Vina Del Mar, Chile. His paper, "Chronic Relapsing Pancreatitis—Fate of Fifty-Six Cases Observed Since 1939-43 Inclusive," was written in collaboration with **Drs. A. H. Baggenstoss** and **J. T. Priestly.**

* * *

Dr. Kenneth W. Teich, Duluth obstetrician and gynecologist, was a participant in the seventh annual meeting of the Academy of Psychosomatic Medicine. He was a member of a panel which discussed psychosomatic aspects of sterility and frigidity at a luncheon. Dr. Teich also served as co-chairman of the convention's press room in his capacity as a member of the Academy's executive committee.

* * *

Mayo Clinic heart surgeon, **Dr. John W. Kirklin,** appeared on the program of the annual scientific meeting of the American Academy of Pediatrics in Chicago. He spoke on "Cardiovascular Emergencies." **Dr. George B. Logan,** also of the Mayo Clinic, conducted a scientific round table discussion on pediatric allergy at the same meeting.
